II

PUBLIC LAW 88-246, 88TH CONGRESS, S. 2311,
DECEMBER 30, 1963

AN ACT To provide for the preparation and printing of compilation of materials relating to annual national high school and college debate topics.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Librarian of Congress is authorized and directed to prepare compilations of pertinent excerpts, bibliographical references, and other appropriate materials relating to (1) the subject selected annually by the National University Extension Association as the national high school debate topics and (2) the subject selected annually by the American Speech Association as the national college debate topic. In preparing such compilations the Librarian shall include materials which in his judgment are representative of, and give equal emphasis to, the opposing points of view on the respective topics.

Sec. 2. The compilations on the high school debate topics shall be printed as Senate documents and the compilations on the college debate topics shall be printed as House documents, the cost of which shall be charged to the congressional allotment for printing and binding. Additional copies of such documents may be printed in such quantities and distributed in such manner as the Joint Committee on Printing directs.

Approved December 30, 1963.

FOREWORD

The 1984-1985 intercollegiate debate topic is "Resolved: that the U.S. Federal Government should significantly increase the exploration and/or development of space beyond the Earth's mesosphere."

In compliance with Public Law 88-246, the Congressional Research Service of the Library of Congress prepared this compilation of materials and bibliographic references to assist collegiate debaters in researching this year's topic. The excerpts from books, periodicals, and other documents were selected to provide background information, an overview of the principal issues, and a balance of opposing views. We also included some materials that are not readily available in public or research libraries. Bibliographic references were also chosen to provide a wide range of information and opinions. In selecting items for this reader and bibliography, the Congressional Research Service (CRS) has attempted to sample the wide spectrum of opinions reflected in current literature on these questions. No preference for any policy is indicated by the selection or positioning of articles herein, nor should one infer CRS disapproval of any policy or article not included.

The selected items have been arranged in five sections: history and overview; space law; space exploration and development, including space policy and economic aspects, technology, industrialization, space station, living in space, planetary exploration, and foreign space programs; militarization of space; and resource allocation among competing national priorities. By agreement with the Project Coordinator for the Committee on Intercollegiate Debate and Discussion of the Speech Convention of America, this document does not take into account questions of specific alternative uses of the current or proposed Federal funds devoted to U.S. space programs and the effect that such alternatives might have upon the scope, direction, or viability of the U.S. space program.

U.S. Government documents listed in the bibliography may be found in most U.S. Government depository libraries which can be identified by your local public library. The Library of Congress cannot distribute copies of these or other materials to the debaters.

Information is included at the end of this volume on guides to additional resources and other publications and associations that may be useful in expanding and updating this compilation. Finally, there is included a list of relevant publications that are available for purchase from the Superintendent of Documents, Government Printing Office.

B. F. Mangan, Senior Bibliographer in Science, Library Services Division, and Marcia Smith, Specialist in Aerospace and Telecommunications Systems, Science Policy Research Division, selected the items included in this reader. In addition, they compiled the bibliography, and Ms. Mangan prepared the guide to additional research sources. Dagnija Sterste-Perkins, Foreign Affairs and National Defense Division, and others offered assistance and suggestions on subtopics of the debate issue. Sherry Shapiro, Library Services Division, coordinated the preparation of this debate manual for publication. Ann Eschete secured copyright permissions, and with Lisa Barker and C. Lee Burwasser assembled and prepared items for publication. John White and Barbara Hall provided the secretarial production of the bibliography and research guide.

The Congressional Research Service wishes to express its appreciation to those copyright holders that have granted permission for the reproduction of materials. Such permission is acknowledged in each instance.

Good luck to each debater in researching, preparing, and presenting arguments on this year's topic.

Gilbert Gude
Director, Congressional Research Service

56 ¶ The President's News Conference of *March* 26, 1958.

THE PRESIDENT. Good morning. Please sit down.

In the scientific field, I have two or three announcements, the first of which I will read, although the document will be in mimeographed form and you can get it after you leave here. This one has to do with forthcoming tests.

[*Reading*] In line with what I said to the press on July 3, 1957, the United States will demonstrate the progress our scientists are achieving in reducing radio-active fallout from nuclear explosions.

To this end, for the first time at any test, we are planning to invite the United Nations to select a group of qualified scientific observers to witness at the Pacific Proving Ground this summer a large nuclear explosion in which radio-active fallout will be drastically reduced.

We will also invite—as we have on occasions in the past—a representative group of United States and foreign news media correspondents.

The United States scientists have been making progress in reducing radio-active fallout from nuclear explosions in the hope and belief that basic advances in both the peaceful and military uses of nuclear energy will thus be achieved. The advantages to mankind of continued progress in this field are obvious.

The United States has always publicly announced in advance its

Reproduced from Public Papers of the Presidents of the United States: Dwight D. Eisenhower, 1958. Washington, G.P.O., 1958. p. 232-242.

nuclear testing programs. We trust that the forthcoming tests will provide valuable information to the world. [*Ends reading*]

Now, the next statement is about another document. There has been prepared by my Scientific Advisory Committee a paper that is called, "Introduction to Outer Space." [1] This report, in my opinion, is the most interesting and fascinating thing in this field that I have seen, and I want to make it available to the entire public. Frankly, I am hopeful that all publicity media will find it so interesting that they will give it the widest possible dissemination.

Then, I wanted to make this final statement: I expect to send up shortly recommended legislation providing for civilian control and direction of governmental activities incident to civilian space programs.

As I say, that report will be—is that to be this afternoon or this morning? [*Confers with Mr. Hagerty*] That one you will get this afternoon.

The first one that I read is the one you will get this morning; the other one will be ready this afternoon.

That's all.

Q. Marvin L. Arrowsmith, Associated Press: Mr. President, can you say specifically whether Russia and other Communist nation observers will attend those tests?

THE PRESIDENT. Of course I can't tell what they will accept, but we are hopeful that the United Nations will designate the Scientific Committee for Detection, I believe it is, of Radioactivity—that's about its name. On that committee are U. S. S. R., Czechoslovakia, the United States, U. K., Canada, and a few others. As a matter of fact, Mr. Hagerty can give you also the entire list of nations. [*Confers with Mr. Hagerty.*]

Mr. Hagerty wants me to read the full—the United Nations Scientific Committee on the Effects of Atomic Radiation, that's the name of the committee.

Q. Peter Lisagor, Chicago Daily News: Mr. President, Mr. Khrushchev has in recent weeks hinted that Russia might unilaterally end its atomic tests and stop production of nuclear weapons. My question is: does the administration have any information that this is a real possibility, and how would you view such a Soviet move?

THE PRESIDENT. Well, of course, anything is a possibility. As we have been reporting from time to time, they have undergone a long series of

[1] See Item 57.

tests and I don't know what they will do, of course.

So far as we are concerned, we have been perfectly honest in stating exactly what we expect to do. It has been many months ago that we announced our spring tests; and we have always stated that when there was any reliable agreement for stopping tests, and particularly when this can be connected with elimination of manufacture for weapon purposes, that we would be quite ready to go with the thing.

I don't know anything about the possibility of their making a statement.

Q. John R. Gibson, Wall Street Journal: Mr. President, there has been considerable discussion recently of taxes. Could you say just what the administration's policy is on tax cuts now, particularly as to timing?

THE PRESIDENT. Well, sir, I have tried to be very accurate in what I had to say about it. I have never excluded the possibility that there might come a situation where a tax reduction would seem desirable.

At the same time, I think that every thoughtful person, certainly that I have met and this includes leaders from both parties, views this step or possible step with such seriousness that they are not going to be stampeded into doing it. As a matter of fact, I believe the Secretary of the Treasury has conferred with leaders in the Democratic Party, with the result that we have agreed to do nothing except with bipartisan consultation, at least notification of intention.

All sorts of difficulties arise with the possibility of tax reduction. Most of you have been aware of some of the anxiety voiced by our people for larger and larger military appropriations. Those appropriations by '59 will be very considerably greater than they are now.

There have been all sorts of other proposals for expenditures that will swell national budgets if all of them are approved.

So, in any event, there seems to be the prospect of very greatly increased expenditures.

Now, if you recognize that any tax cut is bound to increase the gap between revenues and expenditures, realizing again the seriousness of large and continuing deficits upon our whole fiscal and financial system, then you will see that this is not something to do lightly.

I do say that we are watching every development as closely as we know how. We try to get advice, information, counsel from every phase of our American life, and we are certainly going to do those things we think

should be done; but we are not going into a tax cut or any other what we believe to be unwise program that can hurt us badly in the future. We have got to think of the years to come as well as the immediate month in which we are living.

Q. Chalmers M. Roberts, Washington Post: Mr. President, to go back to the nuclear testing for a moment: have you had the report from Dr. Killian on the feasibility of test detection if there were an agreement?

THE PRESIDENT. I didn't understand the question correctly—feasibility?

Q. Mr. Roberts: Have you had a report from Dr. Killian on the feasibility of detecting tests in the Soviet Union if there were an agreement, and do your earlier remarks indicate that there is no truth in the reports that you might consider separating the test ban from the production cutoff?

THE PRESIDENT. Mr. Roberts, as I have told you time and again, certainly I believe it would be unwise to take a perfectly rigid position in respect to any of these things where any agreement would seem to be a reliable one, and would seem to be opening the door to wider and better negotiations with the Soviet Union.

Now, I have not only had many conferences with Dr. Killian, but with others in the scientific world about the feasibility of detecting tests.

While I think there is certainly a little field for uncertainty, and some differing opinion, I think that by and large for any sizable test of any kind, if it didn't go way down into the, you might say, fractional kiloton, that the tests ought with proper inspectional facilities, seismic and electronic, and so on, that they ought to be detected.

Q. Robert C. Pierpoint, CBS News: Mr. President, in view of the long exchange of messages that you have had with the Soviet Union, and particularly the most recent message from the U. S. S. R., do you believe that Summit talks are closer or further away?

THE PRESIDENT. Well, that is a very difficult guess to make, you might say.

This is what I am trying to do: I am trying to maintain a position that I think is conciliatory, that will reflect reasonableness and logic and truth as we see it.

Now, we simply, as I see it, must not by going to a Summit meeting appear to accept every contention that the Soviets are now making. In other words, we must not tacitly say "Yes, we approve of everything that

they are now saying as possible subjects for conversation." It isn't necessarily true or acceptable to us. As I say again, we must be careful to prepare these meetings properly.

Q. Mrs. May Craig, Portland (Maine) Press Herald: Mr. President, although there is plenty of food in this country, many families, especially children and most especially the unemployed, cannot buy because the prices are so high. Have you ever considered the so-called Brannan plan by which the food stuffs went into the market and at whatever price it would bring and the Government pays the farmer the difference between that and parity?

THE PRESIDENT. Well, Mrs. Craig, yes, I have read it often, read about it, discussed it, and frankly I do not believe in the Brannan plan.

Now, I do say this: with our surpluses, I believe that we could find better ways at times such as these of using our surpluses better. And we are doing this more generously and more freely at this moment. But I just don't believe that you can get such a program as this, and work it in our country and keep farmers free.

Q. Joseph R. Slevin, New York Herald Tribune: Mr. President, do you see any sign of the downward movement of the economy as coming to an end?

THE PRESIDENT. Well, I think there are many factors that would imply that the bottom is certainly close, or possibly even now reached. But we have gone through these factors, about the strength of consumer buying and many things of that kind. I don't see any need this morning for going through all of them. My own feeling is we are going through the worst of it right now.

Q. Kenneth M. Scheibel, Gannett Newspapers: Mr. President, getting back to the farm situation, there are reports that you will veto the farm price freeze measure and then in an administrative action, announce some increase in the supports for crops and for dairy products as you did in 1956. Could you tell us anything about that?

THE PRESIDENT. Well, I am always intrigued by prophecies of what I shall do and how I shall do it.

Now, the bill that we have now is still under study. I've had many conferences with my people, and action will be taken soon.

Q. Sarah McClendon, El Paso Times: Mr. President, back to this food question. There are people out in New Mexico right now who can't even get beans because they can't get them out of surplus food

stocks. They are going hungry. There are some unemployed in this country who can't get anything but starches to eat, and that has been going on for months. Can't we do something to give better distribution of surplus foods or to get meat into the surplus pile so that we can give these people a balanced diet?

THE PRESIDENT. Well, right now, if you can take beef at over 30 cents and pork, over 20, and call it surplus, you'll be doing something. I don't see how you can do it. I don't see how meat can be in surplus.

Now, as to methods that there may be for feeding the hungry, after all, one of the things that I am attempting to do by this extension of the benefits of unemployment insurance is to take the burden off the States for what they have to do in assistance within the States and, therefore, give them more opportunity to take care of people that are not taken care of by an extension of this kind. I believe—did I sign that this morning? [*Confers with Mr. Hagerty*] I believe it is either down today, or on the route.

But I agree with you, something should be done for people that are hungry, but we must not just always say that it has got to be right square here from Washington, that we are going to send this and that. We must do our part, respecting the responsibilities, the rights of the States, and if we do our things in that formula, I think we won't go too badly wrong.

Q. Edward P. Morgan, American Broadcasting Company: Another domestic matter, Mr. President. Little Rock is still unsolved. There are responsible reports indicating indeed that the basic issues are more embittered and in a worse state of ferment than they have been before.

Your Civil Rights Commission exists but it hasn't really got its work off the ground and hasn't really got a budget of its own.

Do such things indicate an inclination on the part of the administration to follow rather than lead these civil rights problems to a decision; or, on the other hand, do you have in mind some intensification of pressure on the part of the Federal Government toward them?

THE PRESIDENT. Well, now, just a minute. Intensification of Federal activity can mean many things, and certainly I would have to know exactly what you were proposing before I would believe it to be legal and proper and desirable.

Now I have preached, since the day I came to this office, and long

before, that we are going to solve some of these great internal social problems of the United States of America by reason, by education, by tolerance of the other fellow's views.

I do not believe that all of these problems can be solved just by a new law, or something that someone says, with teeth in it. For example, when we got into the Little Rock thing, it was not my province to talk about segregation or desegregation. I had the job of supporting a Federal court that had issued a proper order under the Constitution, and where compliance was prevented by action that was unlawful.

I had to do that, and that is an entirely different thing from me starting out new laws for attacking this basic problem, which I again say is not going to be solved finally until it is done by understanding and reason.

Now, on the other hand, with respect to your reference to the Commission, surely it has had a hard time getting off the ground. We had to give it, you might say, a loaned budget, but I have great hopes for what it will do in both these fields, watching and seeing what are the legal difficulties that occur, as well as what can be done in helping to get things done in what you might call the educational and even, indeed, the spiritual field.

Q. Frank van der Linden, Nashville Banner: Sir, Senator McClellan's investigating committee has just come out with their report criticizing the Teamsters' Union and a few others on the grounds of alleged corruption, and proposing several laws to promote union democracy through secret ballots, and so forth. Is it your hope that Congress will pass some legislation along those lines before it goes home this year? I know you recommended——

THE PRESIDENT. I have a very fine answer for you. If you will just read again exactly what I said in my special message, I think it was in late January, on labor, you will find exactly what my views are.

Q. John Scali, Associated Press: Mr. President, recently you told us, sir, that you would be willing to hold a Summit conference in the United States if you thought it would contribute to peace. Since then there have been reports that the administration felt that Geneva might be a better site, particularly in view of the feeling that Mr. Khrushchev might use a visit to the United States for his own propaganda purposes. Could you tell us what your latest view on this is, sir?

THE PRESIDENT. I have no change in the views that I have already

expressed, but I will tell you this: by no means do I fear the results on America of a visit by Mr. Khrushchev.

Q. Richard L. Wilson, Cowles Publications: Mr. President, some of your critics claim that you are not doing enough to combat the recession, that to wait until the middle of April is too late.

I wonder if you could discuss that point?

THE PRESIDENT. I think I explained it rather thoroughly in connection with my remarks on tax reduction. I think that we have got to be very, very careful of what we are doing to this economy over the years as well as just looking at the immediate difficulties in which we find ourselves; to fail to do so, to my mind, is merely to bring on again a difficulty that could be even worse. We can compound difficulties here. So, I can run through again for you all the things that we have put down on paper, the recommendations I made to the Congress. They are numerous, and I think mostly they are reasonable, but I do believe that if we go frantic on this, like some people wanted to do on Sputnik, we can be doing the wrong thing.

Q. Raymond P. Brandt, St. Louis Post-Dispatch: Have you and your advisers projected the spending of this Congress so that you can make an estimate on the deficit for the current fiscal year and next year?

THE PRESIDENT. Well, I'll tell you, we tried a little bit, but you can't do it. For example, the housing bill now before me was first started off at $2.9 billion; and now we have got one item in the housing bill, $1.5 [billion] that means, as far as I can see, just right square out of the Treasury as quick as they come in and recommend that the Government purchase these insured loans. So you just can't tell what is going to happen until we are further along in the session I think, as far as the amounts are concerned. But I do think this: it would be futile to believe we could keep the amounts down to what they are now.

Q. Rod MacLeish, Westinghouse Broadcasting Company: Mr. President, going back to the Summit conference for a moment, sir, Mr. Pierpoint commented on the long exchange of letters between you and Premier Bulganin. The Russians seem prompted by some sense of immediate urgency to have a Summit conference, more than usual. Have you any comment on what might be giving them this sense of urgency?

THE PRESIDENT. Well, I really believe it is their hoped for effect upon the world at large. By saying these things, by seeing in the papers

what they purport to mean, they believe they are getting the world convinced that Russia really wants peace and negotiated agreements that are sound and practical and fair to both sides and enforceable.

Now, that is what they, it seems to me, are trying to get over. Now, when you take ourselves, and we try to analyze these things—remember, we are handicapped by the attempt at least to observe fact and truth—why sometimes our answers may not seem as convincing; and if they think they are getting a propaganda advantage, there it is.

Q. Dayton Moore, United Press: Mr. President, there are reports that many people are holding off from buying automobiles to wait and see whether there is a cut in the excise tax. If there should be such a cut, do you think it should be retroactive?

THE PRESIDENT. Well, I'm not going to answer that question directly for the simple reason I don't want yet to discuss the details of any such proposal before you until I believe that necessity is here.

But I will say this: I believe that the American public now should be buying on the basis of the worth of the product that is offered to them. I believe that there is a great field for expansion of business by better salesmanship on the part of business concerns. I believe we have got great savings, I believe that we have got to offer things in a better packaged way, we've got to do better advertising; and above all things let the public buy when they think they are getting a bargain and not worrying about what is going to be some possible future action.

Q. John Herling, Editors Syndicate: Mr. President, this has to do with the reciprocal trade agreement. As you know, sir, many Senators and Congressmen are concerned about the possible adverse effects on their communities of the renewal of the reciprocal trade agreement legislation in general. However, many of them believe they could vote for the renewal of such an important measure if there were less stress and strain and less opposition back home, if an amendment were added in the form of a trade adjustment act, which would aid labor and industry and communities generally which might be adversely affected by the operations of the reciprocal trade agreements legislation.

Is there any prospect that you and the administration would support such an amendment of the reciprocal trade act?

THE PRESIDENT. Well, the only amendment I can think would be more useful was that you could go back to 50 percent above the 1934

38-036 O - 84 - 2

tariff levels in order to protect a particular industry when there was clear evidence that it was being threatened.

Now, I don't know of any other amendment that we have thought of, and I don't know what you could be thinking of.

Q. Mr. Herling: Well, sir, aside from the peril point angle, there is legislation introduced which would physically and economically aid communities that might be adversely affected.

THE PRESIDENT. Oh, you mean direct, some kind——

Q. Mr. Herling: Direct subsidy, yes.

THE PRESIDENT. Well, whatever you can——

Q. Mr. Herling: The Randall Commission report, for example.

THE PRESIDENT. Well, there, of course, there have been all sorts of things suggested even to the degree of assisting a small industry that wants to go into something else, and giving it Federal help while it gets going on something that's more profitable for it, and all sorts of things. None of them as far as I know have been written into legislation, but there is, of course, all of this concern about the so-called depressed areas by giving greater intensity to your procurement efforts in those areas, wherever you can. Everything of that kind has been done that I know of, but the idea you are now propounding, I don't——

Q. Mr. Herling: If specific legislation were laid out, would you consider it?

THE PRESIDENT. I would have to take a look at it.

Q. William V. Shannon, New York Post: Mr. President, I want to clear up something at the last press conference.

You said that you didn't recall that Mr. Dulles had used the word "fraud" in describing the Russian conference proposal. In checking the transcript, it shows that he did definitely use both the words "fraud" and "hoax," and my question is: are you still convinced that there is no difference between yourself and Mr. Dulles in your attitude on this question?

THE PRESIDENT. Well, I would say that Secretary Dulles and I confer by telephone or personally at least 5 to 6 hours a week, more than that if you would count both Cabinet and National Security Council.

Before he made his statement yesterday morning, we talked for, starting the afternoon before and for the morning, another considerable period. I wouldn't guess its length.

Now, if there are any great differences between Secretary Dulles and

myself, I am unaware of them. I have told you time and again I believe he is the most informed and wisest man in the field of international relations that I know, and I certainly have no great differences with him.

Q. Donald H. Shannon, Los Angeles Times: Mr. President, this is an area where you are being accused of doing too much, if you did it.

There are in circulation in Pennsylvania now badges bearing your picture and a ribbon attached to the badge that says: "I like Stassen for Governor."

Did you authorize this, and, if it was not authorized, what do you think of it? [*Laughter*]

THE PRESIDENT. Did you say you have seen that or did you just——

Q. Mr. Shannon: Yes, sir; I have seen the picture; there is one in this room.

THE PRESIDENT. The only thing I can say is this: I have always refused in advance of any primary or of any selection of Republican candidate for any office to intervene in any way, and I wouldn't want to be used either directly or indirectly in such a campaign.

Marvin L. Arrowsmith, Associated Press: Thank you, Mr. President.

NOTE: President Eisenhower's one hundred and twenty-ninth news conference was held in the Executive Office Building from 10:28 to 10:58 o'clock on Wednesday morning, March 26, 1958. In attendance: 234.

73 Statement About the Future of the United States Space Program. *March 7, 1970*

OVER the last decade, the principal goal of our Nation's space program has been the moon. By the end of that decade men from our planet had traveled to the moon on four occasions and twice they had walked on its surface. With these unforgettable experiences, we have gained a new perspective of ourselves and our world.

I believe these accomplishments should help us gain a new perspective of our space program as well. Having completed that long stride into the future which has been our objective for the past decade, we must now define new goals which make sense for the seventies. We must build on the successes of the past, always reaching out for new achievements. But we must also recognize that many critical problems here on this planet make high priority demands on our attention and our resources. By no means should we allow our space program to stagnate. But—with the entire future and the entire universe before us—we should not try to do everything at once. Our approach to space must continue to be bold—but it must also be balanced.

When this administration came into office, there were no clear, comprehensive plans for our space program after the first Apollo landing. To help remedy this situation, I established in February of 1969 a space task group, headed by the Vice President, to study possibilities for the future of that program. Their report was presented to me in September. After reviewing that report and considering our national priorities, I have reached a number of conclusions concerning the future pace and direction of the Nation's space efforts. The budget recommendations which I have sent to the Congress for fiscal year 1971 are based on these conclusions.

Three General Purposes

In my judgment, three general purposes should guide our space program.

One purpose is exploration. From time immemorial, man has insisted on venturing into the unknown despite his inability to predict precisely the value of any given exploration. He has been willing to take risks, willing to be surprised, willing to adapt to new experiences. Man has come to feel that such quests are worthwhile in and of themselves—for they represent one way in which he expands his vision and expresses the human spirit. A great nation must always be an exploring nation if it wishes to remain great.

A second purpose of our space program is scientific knowledge—a greater systematic understanding about ourselves and our universe. With each of our space ventures, man's total information about nature has been dramatically expanded; the human race was able to learn more about the Moon and Mars in a few hours last summer than had been learned in all the centuries that had gone before. The people who perform this important work are not only those who walk in spacesuits while millions watch or those who launch powerful rockets in a burst of flame. Much of our scientific progress comes in laboratories and offices, where dedicated, inquiring men and women decipher new facts and add them to old ones in ways which reveal new truths. The abilities of

Reproduced from Public Papers of the Presidents of the United States: Richard Nixon, 1970. Washington, G.P.O., 1971. p. 250-253.

these scientists constitute one of our most valuable national resources. I believe that our space program should help these people in their work and should be attentive to their suggestions.

A third purpose of the United States space effort is that of practical application—turning the lessons we learn in space to the early benefit of life on earth. Examples of such lessons are manifold; they range from new medical insights to new methods of communication, from better weather forecasts to new management techniques and new ways of providing energy. But these lessons will not apply themselves; we must make a concerted effort to see that the results of our space research are used to the maximum advantage of the human community.

A Continuing Process

We must see our space effort, then, not only as an adventure of today but also as an investment in tomorrow. We did not go to the moon merely for the sport of it. To be sure, those undertakings have provided an exciting adventure for all mankind and we are proud that it was our Nation that met this challenge. But the most important thing about man's first footsteps on the moon is what they promise for the future.

We must realize that space activities will be a part of our lives for the rest of time. We must think of them as part of a continuing process—one which will go on day in and day out, year in and year out—and not as a series of separate leaps, each requiring a massive concentration of energy and will and accomplished on a crash timetable. Our space program should not be planned in a rigid manner, decade by decade, but on a continuing flexible basis, one which takes into account our changing needs and our expanding knowledge.

We must also realize that space expenditures must take their proper place within a rigorous system of national priorities. What we do in space from here on in must become a normal and regular part of our national life and must therefore be planned in conjunction with all of the other undertakings which are also important to us. The space budget which I have sent to Congress for fiscal year 1971 is lower than the budget for fiscal year 1970, a condition which reflects the fiscal constraints under which we presently operate and the competing demands of other programs. I am confident, however, that the funding I have proposed will allow our space program to make steady and impressive progress.

Six Specific Objectives

With these general considerations in mind, I have concluded that our space program should work toward the following specific objectives:

1. We should continue to *explore the moon*. Future Apollo manned lunar landings will be spaced so as to maximize our scientific return from each mission, always providing, of course, for the safety of those who undertake these ventures. Our decisions about manned and unmanned lunar voyages beyond the Apollo program will be based on the results of these missions.

2. We should move ahead with bold *exploration of the planets and the universe*. In the next few years, scientific satellites of many types will be launched into earth orbit to bring us new information

about the universe, the solar system, and even our own planet. During the next decade, we will also launch unmanned spacecraft to all the planets of our solar system, including an unmanned vehicle which will be sent to land on Mars and to investigate its surface. In the late 1970's, the "Grand Tour" missions will study the mysterious outer planets of the solar system—Jupiter, Saturn, Uranus, Neptune, and Pluto. The positions of the planets at that time will give us a unique opportunity to launch missions which can visit several of them on a single flight of over 3 billion miles. Preparations for this program will begin in 1972.

There is one major but longer-range goal we should keep in mind as we proceed with our exploration of the planets. As a part of this program we will eventually send men to explore the planet Mars.

3. We should work to *reduce substantially the cost of space operations.* Our present rocket technology will provide a reliable launch capability for some time. But as we build for the longer-range future, we must devise less costly and less complicated ways of transporting payloads into space. Such a capability—designed so that it will be suitable for a wide range of scientific, defense, and commercial uses—can help us realize important economies in all aspects of our space program. We are currently examining in greater detail the feasibility of reusable space shuttles as one way of achieving this objective.

4. We should seek to *extend man's capability to live and work in space.* The Experimental Space Station (XSS)—a large orbiting workshop—will be an important part of this effort. We are now building such a station—using systems originally developed for the Apollo program—and plan to begin using it for operational missions in the next few years. We expect that men will be working in space for months at a time during the coming decade.

We have much to learn about what man can and cannot do in space. On the basis of our experience with the XSS, we will decide when and how to develop longer-lived space stations. Flexible, long-lived space station modules could provide a multipurpose space platform for the longer-range future and ultimately become a building block for manned interplanetary travel.

5. We should *hasten and expand the practical applications of space technology.* The development of earth resources satellites—platforms which can help in such varied tasks as surveying crops, locating mineral deposits, and measuring water resources—will enable us to assess our environment and use our resources more effectively. We should continue to pursue other applications of space-related technology in a wide variety of fields, including meteorology, communications, navigation, air traffic control, education, and national defense. The very act of reaching into space can help man improve the quality of life on earth.

6. We should *encourage greater international cooperation in space.* In my address to the United Nations last September, I indicated that the United States will take positive, concrete steps "toward internationalizing man's epic venture into space—an adventure that belongs not to one nation but to all mankind. I believe that both the adventures and the applications of space missions should be shared by all peoples. Our progress will be faster and our accomplishments will be greater if nations will join together in this effort,

both in contributing the resources and in enjoying the benefits. Unmanned scientific payloads from other nations already make use of our space launch capability on a cost-shared basis; we look forward to the day when these arrangements can be extended to larger applications satellites and astronaut crews. The Administrator of NASA recently met with the space authorities of Western Europe, Canada, Japan, and Australia in an effort to find ways in which we can cooperate more effectively in space.

It is important, I believe, that the space program of the United States meet these six objectives. A program which achieves these goals will be a balanced space program, one which will extend our capabilities and knowledge and one which will put our new learning to work for the immediate benefit of all people.

As we enter a new decade, we are conscious of the fact that man is also entering a new historic era. For the first time, he has reached beyond his planet; for the rest of time, we will think of ourselves as men *from* the planet earth. It is my hope that as we go forward with our space program, we can plan and work in a way which makes us proud *both* of the planet from which we come *and* of our ability to travel beyond it.

NOTE: The statement was released at Key Biscayne, Fla.

On the same day, the White House released the transcript of a news briefing about the United States space program by Dr. Thomas O. Paine, Administrator, National Aeronautics and Space Administration.

On March 15, 1970, the Office of Science and Technology released a report by the Space Science and Technology Panel of the President's Science Advisory Committee entitled "The Next Decade in Space" (Government Printing Office, 63 pp.). The report set out in detail the administration's space program as outlined in the President's statement.

264 ¶ Statement by the President on U.S. Achievements in Space. *August* 17, 1960

THE EVENTS of the past weeks have demonstrated beyond all doubt the vigor, capabilities and leadership of the United States in the conquest of the frontiers of science and technology and, in particular, in the exploration and utilization of space. The entire nation is proud of the impressive array of successful experiments carried out by the United States this year:

—Pioneer V, the sun satellite, which continued to receive and transmit radio messages over a period of three months and to a distance of 22,500,000 miles from earth;

—Tiros I, the meteorological satellite which took 23,000 cloud cover pictures during its operating life of three months and provided increased assurance that revolutionary improvements in the science of weather forecasting will be achieved;

—the success that has attended the efforts in the satellite-based navigation program called Transit I;

—the orbiting of Echo I, the 100-foot balloon which circles the earth at a distance of approximately 1000 miles and a speed in excess of 15,000 miles per hour serving as a reflector of radio signals from one point to another and distant point on the surface of the earth;

—the record-breaking flights of the X–15 research airplane;

—and finally, the spectacular recovery of the data capsule of the Discoverer XIII satellite.

All these are the results of a well planned and determined attack on this new field—an attack that promises very real and useful results for all mankind. Each of these satellites is destined to play an important part in broadening man's understanding of the cosmos in which he lives. While no one of them has been undertaken solely in an effort to achieve a "spectacular first" in the eyes of the world, each has resulted in just such a "spectacular first" in support of the desires of mankind for greater knowledge and understanding.

The United States leads the world in the activities in the space field that promise real benefits to mankind.

SPACE 25

Not so long ago space was prisfine. Even in the two decades following the orbiting of Sputnik, the two superpowers—the United States and the Soviet Union—were still the only truly significant actors there. And though they had previously launched some impressive unmanned satellites, their first astronauts were little more than tourists in space.

Even the magnificent moon landing was no more a precursor of human colonization of a new "continent" than was the first landfall by the Vikings in North America. And until recently most discoveries about the far universe were being made from earth-based telescopes.

But now, as we approach the twenty-fifth anniversary on October 1 of the day the U.S. National Aeronautics and Space Administration opened for business, much has changed.

A handful of satellites, several of them built or launched by European nations, are revolutionizing our understanding of the universe. In the United States private entrepreneurs have discovered space-for-profit, and businesses of all kinds are being formed to exploit the next 25 years of space activity. Around the globe developing nations are using communications satellites to catapult them into the twentieth century, while at the same time clamoring in international forums for a piece of the action in space. Suddenly laws governing the use of space are critically needed, but have yet to be written.

Even more important, the concept of space as a weaponless sanctuary—so reassuring to the world's citizenry during the first decades of man's journey into space—is threatened by the antisatellite weapons programs of the United States and the Soviet Union.

Symbolically and practically, now is a good time to assess where human beings are and where they are headed in space. With the help of expert authors and scores of space authorities, *Spectrum* examines in the following pages the profound changes that have taken place in man's use of space and considers their implications for the next quarter century. Join us as we voyage through "Space 25."

I. CROSSROADS IN SPACE

By all indications, the human race has reached a critical threshold in space. Man's first quarter century in space has been characterized by the establishment of unmanned probes and ephemeral manned outposts primarily by two pioneer nations, the United States and the Soviet Union. Now, many of the world's nations, private entrepreneurs, and the military establishments of the two superpowers are active in space. And in its silver anniversary year, the U.S. National Aeronautics and Space Administration is about to ask for a permanently manned space station. So mankind has reached a series of crossroads in space in many different arenas, and the paths chosen during these next several years will determine where we are when NASA turns 50 in the year 2008. Among the critical questions are these, broached in separate articles in this section:

- When is it advantageous to use man and when machine in space?
- What role should national military establishments play in space? Will antisatellite weapons, like those the Soviets have tested in the last decade and a far more sophisticated one test-launched from an F-15 jet by the United States last month, imperil world stability? Is it time for treaty talks?
- Will the internationalization of space—with more and more nations actively involved—bring those nations together in cooperative ventures and hence be a force for peace in the world? Or will it create another arena for national competition and associated frictions?
- Will commercial opportunities in space—now burgeoning in launching services, communications networking, earth-observation services, and proposed manufacturing in space—bring people together in fruitful enterprises that could raise living standards on Earth? Or will they be yet another source of international friction and further isolate the citizens of the poorest nations of the globe?

In this first section of *Spectrum*'s space issue, the editors and two expert authors examine each of these crossroads in turn—issues that blur in real life.

As an example, consider the complex debate now taking place at senior levels of the British government. As told to *Spectrum* by a government source, in 1985 the British hope to launch the first of three military communications satellites needed to enhance their current Skynet system. As important members in the European Space Agency (ESA), the British might be expected to select the ESA's French-built Ariane rocket as their launching vehicle. But some in the government prefer to use the U.S. Space Shuttle to launch the new satellites.

The critical issues in the debate have not been publicly identified by British authorities, but *Spectrum* has learned that with regard to national security, some officials feel more comfortable with the shuttle because of the experience the U.S. military and NASA have had with classified payloads. But this does not take politics into account. On one hand, the British worry about what they view as the present U.S. Administration's "troublesome" technology-transfer policies, fearing that these could hamper future cooperation. On the other, there are obvious personal and political affinities between Prime Minister Margaret Thatcher and her conservative government and President Ronald Reagan and his team.

Then there are economic concerns. Considering the British interest in the financial well-being of ESA, it might be in their long-term economic interest to launch with Ariane. However, the Ariane, though successful in its most recent bid to launch two satellites into orbit, lost two expensive payloads on a previous attempt.

This one case highlights many of the crucial issues being faced as man continues his adventure into space. Activity there is becoming increasingly complex, and the articles below attempt to elucidate what lies ahead.

HUMANIZATION: MAN OR MACHINE?

Since 1964, the National Aeronautics and Space Administration has advocated that the United States orbit a space station as the next logical step in the conquest of space. Now it appears likely that a Presidential task force—set up last April 11 under the chairmanship of National Security Advisor William Clark to study the idea—will this month recommend to President Ronald Reagan that the nation go ahead with the project, and a favorable response is expected.

Less certain, however, is whether the space station will actually be built in the 1980s. One problem is the multibillion-dollar cost of the project. In addition, the idea is vociferously opposed by many scientists who have been active in the unmanned space program and who have frequently criticized the manned projects in the past. However, it is supported by many in the aerospace industry and in Congress. The argument between the two groups represents yet another chapter in a debate that has surrounded the U.S. space program for two decades. The disputed question is: What are the proper roles of man and machine in space?

Arrayed in opposition to the space station are such leading figures in U.S. space research and in the exploitation of space as Louis Friedman, former director of advanced programs at the Jet Propulsion Laboratory and now executive director of the Planetary Society; Thomas Gold, an astrophysicist and former member of the Presidential Science Advisory Committee;

Eric J. Lerner Contributing Editor

(c) 1983 IEEE. Reprinted, with permission, from IEEE SPECTRUM, Vol. 20, No. 9, pp. 26-98, September 1983.

Harold Rosen, vice president of Hughes Aircraft and the chief designer of many communications satellites; Freeman Dyson, the physicist and space scientist; and James Van Allen, the discoverer of the Van Allen Radiation Belts.

While these men, though distinguished, are unlikely to have the political clout to kill the space station, their arguments will be used by space-station opponents in Congress and elsewhere. Now, as in the past, these men have contended that the focus on manned space flight, which has absorbed four fifths or more of NASA's expenditures [see illustration, p. 32], has unbalanced the space program, squeezing out unmanned missions with far greater scientific and utilitarian payoffs. They have argued that there are few tasks in space that humans can accomplish more effectively or cheaply than machines.

And some of them believe that the U.S. manned space program is shaped not by its own logic or development, but by such external factors as the economic requirements of the aerospace industry, NASA's own institutional drives, and the pushes and pulls of national prestige. The result, the critics argue, has been a haphazard series of expensive spectacles that have hampered rather than advanced the exploration and exploitation of space.

NASA's leaders and their supporters have in turn replied that, in the long run, human flexibility will more than compensate for the greater expense of sending men rather than machines into space. Far from starving unmanned exploration, manned-mission supporters say, the public and political support for space generated by the man-in-space approach has made possible the allocation of substantial sums toward space science in general. Supporters also contend that without the technology developed for manned space flight, the unmanned missions to the planets would have been impossible. They bridle at the characterization of Project Apollo and other manned space successes—which they consider immense technical accomplishments—as spectacles.

But even some of the harshest critics of today's manned space programs agree that eventually there should be a role for man in space. Also, no director of NASA has ever suggested that all resources be focused on manned space flight. Therefore the real dispute concerns what is to be the balance—for which tasks are men or machines better suited? And what are to be the criteria by which the funds available for space are to be allocated and the plans for space development drawn up?

Some of the key aspects of the controversy are largely economics-based: Are reusable manned vehicles cheaper than expendable unmanned ones? Are space tugs that can commute back and forth between low earth orbit and geosynchronous orbit practical and economical? Other equally important questions have no technical answers: Should scientific exploration, technological development, or national prestige be the highest priority of the space program? Is the maintenance of a U.S. manned presence in space itself a valid justification for space programs?

There have been three critical junctures in this ongoing debate. The first extended from the start of the U.S. space effort, in the wake of Sputnik, to the decision to go to the moon in 1961. The second, from 1968 to 1972, involved the post-Apollo direction of the space program and led to the decision to develop the space shuttle. The third is before us today: it requires laying out the course now that the shuttle is operational.

Four tasks seen for space station

In arguing for a manned space station as the next logical step, Robert Frietag, deputy director of the NASA Space Station Task Force, outlined four main tasks than can be accomplished. First, the station can be used as an orbiting laboratory to perform experiments in space—such as those that study space manufacturing processes, like electrophoresis. "Because of man's flexibility," Mr. Frietag said, "such experiments can be done far more effectively than by preprogrammed satellites or robots."

Thomas Paine, a former NASA director and the recently retired chairman of the Northrup Corp., points to the failure of the unmanned Viking craft to determine whether or not there is life on Mars as an example of a task that robots did not accomplish and that humans could have. Further, the space station can be used as a repair shop for damaged or partly obsolete satellites, Mr. Frietag said. Though the space shuttle is also intended to provide this function, repairs are limited to those that can be performed in the 7 to 10 days that the shuttle is in orbit. More complex repairs require bringing the satellite back to earth and putting it back up again. The space station, according to NASA, would enable a maintenance crew to perform repairs or to replace obsolete modules in a satellite—though the most thorough overhauls would still have to be done here.

"It's like the way the Army maintains its jeeps," explained Mr. Paine. "If you have to replace a spark plug, you do it right there in the field—that's the shuttle. If you need a tune-up, you bring it back to a field service garage—that's the space station. But if there's something major wrong, like the transmission, you have to send it back to the factory—that's returning to earth."

Satellites can also be resupplied from the shuttle or a space station, Mr. Paine added. The infrared astronomical satellite, for example, has less than a year's supply of liquid helium and can be refilled in space. In NASA's view, such repair operations will be cheaper than replacing communications and scientific satellites —especially tomorrow's much larger and more complex ones—even taking into account the added cost of maintaining the manned space station itself.

The third purpose of the space station, Mr. Frietag pointed out, is as a base for the launching of reusable space "tugboats" to take satellites from low earth orbit, where the station would be located, to geosynchronous orbit. This is viewed as cheaper than either direct launching of the satellites from the ground or launching with expendable upper stages from the shuttle.

Finally, the space station can be used as a staging area for the assembly and launching of large interplanetary probes, either manned or unmanned, the NASA official said. The payload would be carried aloft in sections by the space shuttle. Large earth-orbiting power stations, communications complexes, and earth-observation centers and other extended satellites could also be assembled in this way, NASA says, thus modifying the design of satellites and expanding their capabilities.

Differences over economic value

The core of the argument for the space station, including its first three uses, is essentially economic: the station–shuttle combination can more cheaply accomplish what is already being

done in space. But it is on these economic grounds that the space station's opponents attack it most sharply, as they formerly attacked the economic justification of the space shuttle itself.

"There's just not the slightest justification for the space station," said Thomas Gold, an astrophysicist at Cornell University in Ithaca, N.Y. "Since there is no long delay time in getting signals to and from earth orbit, you could have highly detailed operations carried out by remote control from earth."

Dr. Gold, a former member of the Presidential Science Advisory Committee, admitted that present remote-control technology may have to be improved to equal human capabilities fully for direct, hands-on manipulation, but he believes that such a development program would be far less costly than the $10 billion estimated for the space station. In addition, he believes that remote-controlled devices could be used for many other applications, such as underseas operations, mining, and so on. In space, combinations of programmed robots and remote manipulators—mimicking the actions of operators on earth—could, in Dr. Gold's view, not only perform experiments in space, but could also do the assembly tasks that NASA allocates to men, and do them more cheaply.

In rebuttal, Mr. Frietag said: "It just won't work. I don't believe you can build teleoperator robots or remote-control devices that can perform anywhere near as well as men—it can't be done." This, however is not a universally held opinion among present and former NASA officials. Many, including present NASA administrator James Beggs and former administrators such as Mr. Paine and Robert Frosch [see "Hybrids: the best of both worlds," p. 30], agree that NASA needs an expanded robotics program. But in varying degrees, each still argues that even with advanced teleoperators there is a need for men to be on the spot in space.

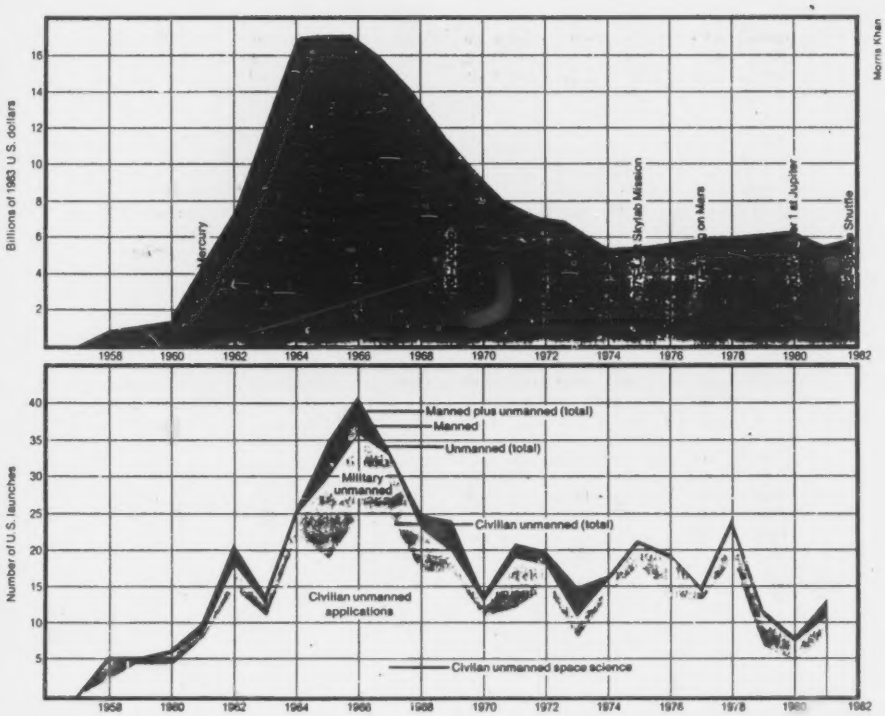
Basic NASA premises challenged

Perhaps even more fundamental is the question of whether many of the tasks assigned to the space station need to be performed at all. "It's incredible to even think about going to geosynchronous orbits, where the communications satellites are, to repair them," commented Dr. Rosen, the communications satellite designer at Hughes Aircraft who invented the Syncom satellite. "It takes far too much energy to get up there and down." Even for satellites in low earth orbit, "all you can do," said Dr. Rosen, "is minor repairs, like refueling their stabilizing rockets—and the shuttle can do that."

Mr. Paine replied that, though admittedly it will be too costly to get people into geosynchronous orbits to do repair work, future satellites in low earth orbit will be designed to be modified by people working in space. "Take the Space Telescope—it may be up there for 20 years or more," Mr. Paine said. "You might want to do an overhaul of the telescope without bringing it back to earth."

Nor would a manned space station be an appropriate place for space science, critics have pointed out. "A single, large platform is the last thing you want for space science," said Dr. Dyson, a physicist with the Institute for Advanced Studies in Princeton, N.J. "You need a large variety of orbits for scientific satellites, each tailored to a given objective. Besides, people get in the way of scientific experiments—they cause vibrations, for example."

This is one area where the space scientists have won a point. In its proposal for a space station [see also "The next 25: agenda for the U.S.," p. 91], NASA describes an entire space infrastructure composed of unmanned platforms—some for scientific experiments—in addition to the manned space base.



The massive rise in NASA spending during the early years of the Apollo program was followed by a fall to a much lower plateau (top graph). Both manned and unmanned space activity boomed while NASA's budget was high. But with the constricted budget of the 1970s and 1980s, during periods of intense manned activity (the moon flights, Skylab, and the space shuttle program) there have been fewer unmanned launches (bottom graph) for civilian applications and space science.

Another argument expressed by Dr. Dyson, is that even for manned exploration of the moon or Mars, a space station would not be useful. "You can see some value in men building a lunar base, for example, but you don't need a space station to do that —in a space station men are just sitting in a can."

NASA Administrator James Beggs disagreed. He told *Spectrum*, "We have been arguing the question of man's proper role literally from the beginning. There are papers around that go back to the Eisenhower years that discuss the question of manned activities versus automated unmanned activities in space, and there are arguments on both sides. We have not to date plumbed the depth of what man can accomplish in space.

"We have some experience from Skylab or Soyuz and of course from Apollo, Mercury, and Gemini that gives us some insights into what man can do. It's fair to say that Skylab, which was an enormously important step in NASA's exploration activities, was successful because the men deployed the solar sails and they put up the shade that was necessary in order to make it work. You might say, it didn't have to be designed for men, except that we did do a lot of precursor work in the Skylab that is just now reaching fruition. For example, the early experiments on electrophoresis in space were done by the men on Skylab, and I think that right now we see a tremendous potential for the experiments that are flying on the shuttle."

Critics of NASA's manned program even question what motivations, other than the avowed goals of the space program, are behind expensive projects like the space shuttle and space station. To Dr. Friedman and even station supporter John Logsdon, director of the Graduate Program in Science Technology and Public Policy at George Washington University in Washington, D.C. [see "NASA's dual challenge: serving yet striving," p. 86], NASA's own institutional existence is a major driving force. "NASA is not a science but a technology agency," Dr. Friedman said. "It is very heavily in favor of the development of capabilities and propulsion systems, not applications and exploration—they want continually to have that one, big project to engineer."

To Dr. Van Allen, a University of Iowa physics professor who is one of the pioneers of the space program, "the interests of the aerospace industry have always been a major factor." The big manned space programs require big, expensive rocket systems.

Willis H. Shapley, director of space and defense affairs in the Bureau of the Budget during the administrations of Presidents Kennedy and Johnson, said that when the decision was made to finance the space shuttle, "the Administration knew there was a big recession in California aerospace and the industry was lobbying very hard for the shuttle."

"It's often hard to know where the pushing from the industry leaves off and the pulling from NASA begins," according to Mr. Shapley, who also served in NASA as an associate deputy administrator for several years. Many officials, including four out of six NASA administrators, had close links with the aerospace industry either before or after their tenures, the argument goes.

But Dr. Logsdon derided such links between industry and NASA, asking: "Who do you want running NASA? Amateurs?" And Mr. Paine points to NASA's successes in communications and meterological satellites as well as its deep probes in space as proof that the space agency has always had a great concern for final goals, not just the technologies needed to achieve them.

Shortchanging of science feared

What concerns the critics of the manned space program is not merely that they consider the space station a waste of money, but that, given the overall constraints on NASA funding, they feel that the manned programs have squeezed out the far more scientifically rewarding unmanned space missions and will continue to do so. Dr. Van Allen, Dr. Gold, Dr. Dyson, and other space scientists believe that the vast majority of the benefits derived from the space program have come from unmanned, not manned, satellites and space probes.

They point to the changes in scientists' views of the solar system as examples. Mars, with its mysterious dry river beds, titanic volcanoes, and huge ice caps; Venus, with its sulphurous and baking surface; Jupiter, with its swirling storms that are larger than the earth; and Europa (one of Jupiter's satellites), possibly the only other body in the solar system possessing liquid water beneath shifting ice caps, have all been explored in the past 25 years by robot spacecraft. In the more utilitarian uses of space, worldwide communications have changed, weather forecasting has improved, and the exploitation of the earth's own natural resources has been enhanced by earth-orbiting satellites.

Manned mission proponents will respond that these very successes contradict those arguing that manned-mission budgetary allocations starve those for unmanned missions. Most of the solar-system missions just named were accomplished contemporaneously with the Apollo program, Mr. Paine pointed out. "They have the conviction," he said of the space scientists, "that the Office of Management and Budget, the White House, and congressional committees have a fixed amount to give NASA. So manned flight budgets come out of the planetary programs, according to them. This model is not realistic."

And yet it is undeniable that the U.S. unmanned space program has been severely cut back in the last decade. Though the overall NASA budget shrunk by two thirds in real dollars, allocations for the shuttle rose and space science and applications were almost squashed out of existence. Launches of civilian space vehicles, which had been running at over 20 per year in the mid-1960s, dropped to 12 to 15 per year in the 1970s and to 7 or 8 per year in the 1980s, when spending for the shuttle peaked.

Following the successful flights of the Viking spacecraft to Mars and the Voyager spacecrafts to Jupiter and Saturn, the solar-system exploration program was nearly eliminated. The U.S. portion of a mission over the poles of the sun, which was to have been performed jointly with the European Space Agency, was canceled (though, in the end, the United States will be contributing half the funds for the European portion of the mission). A Venus radar-imaging orbiter flight (recently resurrected) was originally stopped. And a Jet Propulsion Laboratory proposal for a Halley's Comet mission was rejected. Similarly many earth-orbiting astronomical satellites, such as the Advanced X-Ray Astronomy Facility, have been canceled or delayed, leaving the space telescope as the principal astronomical project of the coming decade.

Still, Thomas Paine is not convinced that the shuttle was the cause of these cutbacks. "Don't you give a major recession any credit?" he asked in an interview with *Spectrum*. "How about all other areas of university research where funding declined during the '70s? Was that due to the shuttle too?"

"There is no question that the space shuttle has delayed the development of space science," said Thomas Donahue, chairman of the National Academy of Science's Space Science Board and a professor of space science at the Carnegie Institution in Washington, D.C. "Once the decision was made at the start of the shuttle program not to go ahead with umanned research in parallel, and to phase out expendable-launch vehicles, the flight opportunities for science packages were reduced drastically."

Man or machine? A 25-year debate

The history of the U.S. space program has been marked by a running debate for 25 years over which goal should have priority—manned or unmanned exploration of space—and which criteria should be used to decide national prestige or space science.

The basic outline of the debate was already clear in the first months following the Soviet Union's October 1957 successful launching of Sputnik, the first man-made satellite. Before 1957 was over, General Bernard Schriever, then chief of the U.S. Air Force Ballistic Missile Division, had set up a committee under the chairmanship of Edward Teller, the nuclear physicist who recommended that the Air Force establish a vigorous space program, with the immediate goal of a manned landing on the moon.

The Air Force plan, dubbed Man in Space Soonest, or MISS, called modestly for a manned landing on the moon by 1965 at a cost of $1.5 billion (about 6 percent of the eventual cost of Project Apollo). Not to be outdone, the Army, with the help of its prized rocket designer, Wernher von Braun, developed its own plan—called Man Very High, later renamed Project Horizon—for getting to the moon by 1965. Though this plan had the more realistic price tag of $17 billion, it had as its far-fetched objective the establishment of a permanent 12-man moon base no later than 1966. The services both started studies aimed at justifying these goals in military terms—such as the use of a moon base to fire nuclear rockets at enemies on earth.

Eisenhower not impressed

President Dwight D. Eisenhower was not impressed by these arguments, and he was strongly supported in his view by his science advisor, James Killian, president of the Massachusetts Institute of Technology. Dr. Killian was skeptical of the military uses of space and urged a mainly scientific space program. Upon his recommendation and that of others, President Eisenhower established the National Aeronautics and Space Administration in April 1958 to oversee these scientific uses of space. However, under strong pressure from the Pentagon, the President did agree to a small initial manned effort, Project Mercury, whose aim was testing to see if man could survive in space.

Once organized, NASA put forward proposals remarkably similar to those of the armed services—not surprisingly, since many of the same men were involved in formulating both sets of ideas. In 1959, at the first meeting of NASA's Research Steering Committee on Manned Space Flight, NASA's Deputy Director George Low proposed a manned space flight that would culminate in a trip to the moon sometime after 1970. This plan was adopted by the committee.

President Eisenhower, still unenthusiastic (he would say later that "anyone proposing to spend $40 billion to get to the moon is nuts"), again turned to Dr. Killian for an assessment of whether the moon shot was scientifically justified. Dr. Killian had a report written by a committee of scientists under Donald Hornig.

The scientists' report concluded that "at the present time, man-in-space cannot be justified on purely scientific grounds." Dr. Killian himself added that "the really exciting discoveries in space can be realized better by instruments than by man." The President rejected NASA's ambitious moon plan, leaving the post-Mercury fate of manned space flight to his successor.

Three events radically changed this apparently dim prospect for manned flight. First, President John F. Kennedy replaced Keith Glennan, the first administrator of NASA, with James Webb. Dr. Glennan had acted as a middleman between those in NASA who were pushing for a manned program and the President who opposed it. And he had sympathy with some of the objections raised by the President's Scientific Advisory Board. Mr. Webb, a former director of McDonnell Aircraft Corp., was by contrast an enthusiastic proponent of the manned space program.

Then on April 12, 1961, the Soviet Union launched Yuri Gagarin into a single-orbit flight. He was the first man in space. President Kennedy was shocked into action. "Is there any place we can catch them?" Mr. Kennedy asked Mr. Webb. "What can we do? Can we go to the moon before them?" Three days later the Central Intelligence Agency's attempt to overthrow the Fidel Castro government in Cuba failed dismally at the Bay of Pigs.

A matter of national prestige

Suffering two blows to U.S. prestige in four days, the President sent a memo to Vice President Lyndon B. Johnson, then chairman of the Space Council, to see if there was any way the resources of the country could be mobilized to overtake the Russians in space "by a laboratory in space, by a trip to the moon, or by a rocket to land on the moon." The decision to send a man to the moon before the end of the decade was announced little more than a month later.

The basic justifications for the decision, in the eyes of those who made it, were summarized in a memorandum to President Kennedy from Mr. Webb and Secretary of Defense Robert McNamara. "It is man, not merely machines, in space that captures the imagination of the world," they wrote.

—*E.J.L.*

Even with opportunities for experimentation on the shuttle, life has become harder for space scientists, in Dr. Donahue's opinion. "Qualifying experiments for the space shuttle is a slow, painful, and costly project," he said, "because the science packages have to meet the rigid specifications of the manned program, which are much tighter than those of unmanned shots." Part of the problem is that astronauts must interact with the experiments, and this greatly complicates their design.

Dr. Dyson and other space scientists fear the problem will become worse if work starts on the space station. But, perhaps ironically, even as it appears that the Administration is about to throw its support behind the space station, so does it appear that the long space science drought may be over.

Might man and machine cohabit the heavens?

Even as the Administration of President Reagan edges closer to approving the space station, so too have the prospects of the unmanned program become considerably brighter, thanks to the efforts of the Solar System Exploration Committee (SSEC). Created by NASA to propose realistic unmanned missions for the next two decades, the SSEC heeded the advice of Presidential Science Advisor George A. Keyworth II, who said that in today's political and economic climate, billion-dollar missions would not be approved by the President. Rather, he challenged space scientists and engineers to propose lower-cost missions.

The SSEC, primarily under the leadership of Noel Hinners, now head of NASA's Goddard Space Flight Center in Greenville, Md., has proposed a minimum budget for the next decade: the spending of $300 million a year for pared-down probes of the planets. The committee's highest-priority projects are a Venus radar mapper (a smaller version of the canceled Venus orbiting imaging radar), a Mars geoscience and climatology orbiter, a probe to Saturn's giant satellite Titan and a rendezvous with a comet and asteroid sometime after the Halley's Comet visitation. As described by Theodore Simpson [see "Solar-system sorties: ending the hiatus," p. 84], the committee hopes to reduce expenses by designing a basic spacecraft, the Mariner Mark II, which could be slightly modified for several of the missions, each

of which would cost no more than $200 million. As Dr. Simpson reported, response to date from the Administration and Congress to the SSEC proposal has been favorable, and the Venus radar mapper is included in NASA's current budget proposal.

Further, in 1984, the SSEC will issue a second part of its report, which will propose a set of more expensive, extremely ambitious programs for unmanned space science. Thus, should there be a sustained recovery of the U.S. economy, which might encourage the current Administration to loosen NASA's purse strings, or should the 1984 Presidential election result in a new administration favoring increased space spending, NASA will be ready.

But whether it will be ready to increase substantially what former Administrator Frosch conceives of as the hybridization of space, by upgrading its programs in the use of automation, is far from clear. Nor is the old debate about how best to use man and machine in space likely to disappear in the foreseeable future. ◆

MILITARIZATION: PEACE OR WAR?

While the news media were pinning the label "Star Wars" on President Ronald Reagan's proposal last March 23 to step up research on ballistic-missile defense, the United States military was slipping quietly into a new era in space. The turning point was a largely unheralded change that had occurred six months earlier beneath Cheyenne Mountain in Colorado.

The granite mountain's hollowed interior has long housed the North American Aerospace Defense Command (Norad); it is here that an enemy missile attack would first be confirmed and an alert sent to the President of the United States and the Prime Minister of Canada. But on Sept. 1, 1982, a second tenant moved into the mountain: a new Air Force organization called Space Command. Its purpose is to consolidate the Air Force's diverse satellites and space programs under a four-star general, James V. Hartinger.

Space Command is the first high-level organization in the military created solely to operate systems in space, inspiring comparisons with the inauspicious beginning of the Air Force as a unit of the Army's Signal Corps. In fact, the Air Force is pressing to make it a unified command, serving as an umbella organization to operate the military space systems of all four services.

A shift in policy under way

This institutional change is occurring on the threshold of a fundamental shift in the military presence in space. Ever since Sputnik I, the first artificial satellite, launched by the Soviet Union in 1957, the major military establishments have used satellites for communications, intelligence, and other military support functions. But for many years, no military organization of any nation deployed orbiting weapons.

The Outer Space Treaty of 1967 forbids placing "weapons of mass destruction" into earth orbit, which includes some early antisatellite weapons that used nuclear explosives. Furthermore, the Antiballistic Missile Treaty of 1972 explicitly forbids tampering with the "national technical means of verification" of the treaty, including intelligence satellites, which are widely recognized as promoting stability. In fact space was long considered a sanctuary until both superpowers developed nonnuclear antisatellite weapons, like the Soviet Union's hunter-killer satellite, which creeps up on other satellites and destroys them by spewing shrapnel. In response to the Soviet weapon, the U.S. Air Force seeks to deploy its own antisatellite weapon, and the Space Command would operate it. In addition, the Department of Defense is planning to spend $243 million next year on research into laser and particle-beam technology for antisatellite and other weapons in space. Last year, for the first time since 1960, the DOD spent more money on space than NASA did. The Soviet Union, according to the U.S. Defense Department, is already spending three to five times more than the United States on developing such weapons.

These events have provoked fears of an arms race in space. Some experts say that the world is at a turning point; unless agreements are made soon to stem the development of space weapons, a Pandora's box will be opened. Experts disagree, however, as to whether a ban on space weapons is even feasible.

The DOD has been criticized also for considering weapons systems that some scientists believe are unworkable—space-based lasers, for example, might entail insurmountable engineering problems of weight, power, beam aiming, and others. Some military specialists say that weapons in space are not valid militarily—in other words, since wars are fought to gain an advantage on the ground, it makes little sense to build elaborate weapons in space.

What impact will the creation of the Space Command have on the introduction of weapons in space?

Before the birth of the Space Command, space technology was largely the province of engineers, not combat commanders. At research and development facilities like the Air Force Space Division, engineers built and launched satellites with little guidance from high-level commanders in other divisions of the Air Force, where the systems often were used. In fact, in the early days of space, recalled John Logsdon, chairman of the Department of Space History of the National Air and Space Museum, very few generals supported extensive use of space technology. "Leaders of the career military tend to be skeptical about changing the way they do business," Dr. Logsdon said. Space enthusiasts could be found in the military, he noted, "but with very few exceptions they were colonels or in the lower ranks—the so-called space cadets."

Recent years, however, have been marked by a growing appreciation by the Air Force leadership of the military importance of space—and a growing dependence on its satellites for communications, intelligence, and the like. By Fiscal 1983, the U.S. military and intelligence space budget had quadrupled in less than a decade to $8.4 billion, and the Air Force decided it was time to place its space programs under an "operational command." The Space Command will identify where space systems are needed and define their specifications. The Space Division, set up years ago, will develop and build the systems, as it has in the past. After the systems are ready for use, the Space Command will control them in peacetime and devise strategies for their use in war. The command will also enter its space systems into interservice military exercises to decide what new capabilities they need.

The Space Command is based on the Air Force's recognition that space is no longer an R&D laboratory but an arena for military operations. The command has geared up quickly for its new responsibilities. Last May it began ground breaking on a $1 billion Consolidated Space Operations Center near Colorado

Fred Guterl Associate Editor
Carol Truxal Contributing Editor

Springs, Colo., which it says will become "the centerpiece for all military operations in space." The center will be equipped to control half of all military satellites, and by the end of the decade it will control DOD flights of the U.S. Space Shuttle, now controlled from NASA's Johnson Space Center in Houston.

Information on the whereabouts of shuttles and satellites will be fed to the center from inside Cheyenne Mountain. Linked to a worldwide network of radar, telescopes, and deep-space cameras around the world [see Fig.], computers now keep track of almost everything in orbit—some 4900 objects, including both useful satellites and chunks of debris—as long as it is larger than a basketball and within 23,000 miles of the earth. This space surveillance network is now operated by Norad. In operation since the early 1960s, it keeps a particular eye on Soviet satellites, on objects falling from orbit (like the U.S. Skylab and the nuclear-powered Soviet Cosmos 954), and on any object that looks like an approaching missile.

But the strength of the military's new commitment to space is measured best not by its awesome facilities, but by the stature of the man who runs them all, General Hartinger. For the last three and a half years, he has been commander in chief of Norad—the man who makes the ultimate decision about whether a heat flash and radar blip picked up by early-warning sensors is indeed a Soviet nuclear attack. Last fall, when Gen. Hartinger became commander of the Space Command, the military space program for the first time was placed under the guardianship of a four-star Air Force general.

"You can't do anything in the military unless you've got a four-star general advocating it," said Hans Mark, deputy administrator of NASA and former secretary of the Air Force. "The real reason for Space Command is to have a four-star general out there with SPACE written across his chest."

Gen. Hartinger calls himself "the honest broker for space in the operational world." He will be advocating, among other things, that space systems be better equipped to survive conflict. The general sees the Soviet space threat as real and as a strong reason for forming the Space Command.

Soviet buildup emphasized

The U.S. Defense Department's booklet, *Soviet Military Power: 1983*, says that in the past 10 years the Soviets have been launching four to five times as many spacecraft each year as the United States. The Soviet Union is also developing a heavy-lift launcher, the booklet notes, "that will be able to place payloads at least six to seven times the weight of those of the U.S. Space Shuttle into orbit."

The launching vehicle will help the Russians develop "a large manned space station by about 1990 to maintain a military presence in space," the booklet continues. The strength of the Soviet manned program is emphasized: it has placed seven space stations in orbit since 1971, enabling cosmonauts to amass "twice as many man-hours in space as U.S. astronauts" have amassed.

Such statistics must be viewed with caution. "There is a real war of rhetoric going on nowadays between the U.S. and USSR about whose space program is more military," said Marcia Smith, a Library of Congress space specialist. In truth, since the Soviet Union does not split its military and civilian space programs into separate organizations, as the United States does with the DOD and NASA, it is hard to determine how much of the Soviet space program is military. U.S. observers can guess whether a Soviet space station is doing at least some military work by whether its cosmonauts are from the military and by the encryption of its telemetry. But the bottom line, added Ms. Smith, is that "it's very difficult to figure out exactly what they are doing up there."

The fact that the Soviet Union launches more satellites than the United States is also misleading. U.S. satellites often are more advanced and stay in orbit longer.

Still, the sheer number of Soviet launchings worries some U.S. generals. "It shows they have a massive infrastructure to mass-produce satellites and boosters," said Major General John H. Storrie, the Air Force's director of space plans and operations in the Pentagon.

The Soviet Union, he fears, may challenge U.S. technological brain with sheer brawn. The Soviet antisatellite weapon is a case in point. Though hardly sophisticated, it works, and it has been tested in space for more than a decade.

The DOD booklet calls the deployment of the Soviet antisatellite weapon a clear sign that the USSR recognizes space as an "arena in which to conduct war." This implies to some U.S. generals that the nation can no longer afford to view space as a sanctuary, a refuge for nonaggressive reconnaissance and communications satellites. The United States needs its own antisatellite weapon, said Gen. Hartinger, "to protect its interests in space."

Gen. Storrie explained, "We feel we are in space right now where we were with airplanes back in World War I. Airplanes were first used for reconnaissance. The German aviators and the French and English aviators would pass each other on their way to the other side's trenches to do their reconnaissance. Then they found out that the commanders who had the best reconnaissance were winning the battles. So one day someone took a .45, and as he passed the other side's plane, took a shot at it. The next day the other plane had a machine gun mounted on its back. And so on, until they were all involved in air battles."

Gen. Hartinger insists that "we are not militarizing space." Yet the Air Force is clearly grappling with a new perception about the role of space in military operations and, with the better space technology and resources now at its command, it is creating the infrastructure needed to translate that perception into reality.

The technology for placing weapons in space already exists. "Everyone says, 'You don't have to worry about lasers and particle beams—they're 20 years away,'" noted Ms. Smith. "The point is you don't need lasers and particle beams to fight a war in space. You can do it with conventional technology. They have it, and we're developing it."

Early uses of space

In 1958 the U.S. Navy began developing its first navigation satellite, Transit 1A. In 1960, three months after the Soviet Union put an end to U.S. spy planes flying over its country by shooting down a U-2, the United States launched its first photographic reconnaissance satellite, Discoverer 13. Two years later the first military weather satellite flew. By the late 1960s, the DOD, bor-

rowing an idea and much technology from NASA, put a military communications satellite into geosynchronous orbit.

These early satellites were so-called support systems; they did not fight battles, but provided crucial services to troops and fleets that did the fighting.

"One must distinguish between the militarization of space and the weaponization of space," said David Williamson, who worked as assistant to the administrator of NASA from 1959 to 1982. "The militarization of space began 25 years ago—that is, the use of space for military functions. They don't have to be aggressive or explosive to be military."

Support satellites continue to be the heart of the military's involvement in space, and hundreds of millions of dollars are spent each year on upgrading these satellites. The next generation of navigation satellites, the Global Positioning System, will enable planes, troops, and ships around the world to pinpoint their positions to within 50 feet by time-ranging radio signals from a constellation of satellites equipped with atomic clocks. The latest communications satellites offer jam-resistant, superhigh-frequency transmissions. The intelligence satellite KH-11, used by the U.S. Central Intelligence Agency, has multispectral scanners with resolution that is "20 to 30 times better than Landsat," speculated Thomas Karas, author of *The New High Ground: Strategies and Weapons of Space-Age War* (New York: Simon & Schuster, 1983).

As the capabilities of such satellites have improved, the U.S. military has grown more dependent on them. For instance, more than two thirds of U.S. long-distance military communications are now carried by satellite. But despite dependence, the military has until recently emphasized the capabilities of fragile devices rather than their capability to survive in war. For years, space was viewed in the United States as a sanctuary and not a potential battle zone. This view was based in part on technological optimism—the feeling that no one could possibly reach U.S. satellites—and in part on the fruits of diplomacy.

For one thing, a series of international treaties signed in the 1960s and early 1970s limited military uses of space. The 1963 Limited Test Ban Treaty outlawed nuclear explosions in space. The 1967 Outer Space Treaty banned the orbiting of "weapons of mass destruction"—taken to mean nuclear bombs and biological, radiological, and chemical weapons. In 1972 the United States and the Soviet Union signed SALT I agreements barring both superpowers from placing antiballistic missile defenses in space and strictly limiting the number of defenses that could be placed on the ground.

The overall effect of such treaties was to create a feeling, as Dr. Logsdon put it, "that you could get away with deploying military systems in space without worrying about protecting them. There was a hope that space would be a sort of military sanctuary."

The race for antisatellite weapons

Ironically, however, by the mid-1960s both superpowers were working on weapons that could undermine that sanctuary—antisatellite (ASAT) weapons.

In 1964, the U.S. Army began tests to see if its Nike Zeus antimissile system could hit satellites, and the Air Force began testing its Thor ballistic missile as an antisatellite weapon. Both weapons, it turned out, had limitations: they could only hit targets that happened to fly overhead, and because the missiles had nuclear warheads, they would release electromagnetic pulses that were likely to disable electrical systems on the ground.

In 1968, the Soviet Union ran the first operational test of its ASAT explosive mine, tucked aboard a small satellite and launched by a modified SS-9 ICBM. It could destroy a satellite by entering an orbit approximating that of the target, slowly creeping up on it, and then exploding, battering the target with shrapnel.

As the USSR continued to test the weapon in the 1970s, the concern it aroused was, to some military observers, out of proportion to the threat, because most U.S. satellites—the communications and navigation satellites and many intelligence satellites—were in orbit higher than the Soviet ASAT could reach. The only nonclassified satellites that are vulnerable are low-flying weather and reconnaissance satellites.

In 1978 President Jimmy Carter started negotiations with the Soviet Union to try to talk it out of developing its ASAT. The talks were unsuccessful. "The Soviets said, 'What about the shuttle? It's a bomb can,'" Mr. Williamson recalled. The talks were suspended, and after the Soviet Union invaded Afghanistan in 1979, they were never resumed.

The Pentagon, however, responded to the Soviet ASAT threat in two ways. First, it placed more emphasis on ensuring that satellites could survive conflicts; it has given many of its satellites at least a modest ability to maneuver out of a weapon's way—a fairly easy defense against the sluggish Soviet ASAT—and it has started to use satellites redundantly. Second, it began developing an ASAT of its own.

The U.S. Air Force plans to test its first ASAT at Edwards Air

Force Base in California. Unlike its simpler Soviet counterpart, the weapon is not launched from the ground but from the air. A two-stage rocket is strapped to the belly of a modified F-15 plane. After the plane takes off, the rocket sends a miniature homing vehicle hurtling toward the target satellite at 8.5 miles per second—15 times faster than a bullet leaves the muzzle of an M-16 rifle, said Dr. Karas. Guided by a long-wave infrared sensor, the homing vehicle maneuvers toward a target by firing tiny rockets on its sides. The changing position of each rocket on the spinning vehicle is monitored by a laser gyroscope. Because the vehicle heads directly for its target, rather than co-orbiting like the Soviet ASAT, it completes its job more quickly—in a matter of minutes after the F-15 launches the rocket.

The Defense Department hopes to have 30 of these weapons by 1987. The United States needs an ASAT, Gen. Hartinger said, since the Soviets appear to be working on a booster that by the end of the decade could threaten even U.S. geosynchronous satellites.

Some critics of the U.S. ASAT argue that such weapons could lead to innocent satellite malfunctions being construed as enemy attacks. This, they say, could lead to an exchange of retaliatory strikes, jeopardizing valuable surveillance and communications satellites and creating an unstable political climate. Some critics argue that a war could be started this way.

Resolutions have been introduced in the U.S. House of Representatives and Senate urging the President to try to negotiate a ban on ASATs with the USSR before the U.S. weapon becomes operational. Some officials say, however, that the Soviets are unlikely to negotiate away a capability that they have and the United States does not yet have.

Are laser weapons next in space?

Daniel Deudney, senior researcher at the Worldwatch Institute, Washington, D.C., believes that if the U.S. ASAT becomes operational the Soviets may counter with an even more capable model, perhaps a laser ASAT orbiting in space. And although an initial Soviet laser weapon would have "negligible capabilities, the psychological impact, as with Sputnik, will probably be traumatic, leading the United States to embark upon an ambitious crash program to put battle stations into orbit. The result will be a full-scale arms race in space," Mr. Deudney said.

The Soviet Union already has a large directed-energy research program, including laser-weapons studies, which the DOD estimates to be from three to five times bigger than its own efforts. Rumors that the Soviet Union is on the verge of deploying a laser weapon have circulated for most of two decades; lately they have been increasingly supported by DOD reports. Robert Cooper, director of Darpa, said during recent testimony before a House panel, "The Soviets could launch the first prototype of a space-based laser antisatellite weapon in the late 1980s or early 1990s."

The appeal of laser beams as weapons is that they have no mass—thus no propellant is required to hit a moving target. Satellites are relatively easy targets for laser weapons, since their fragile electronics can be upset by modest amounts of power. A harder task would be using lasers to destroy incoming ballistic missiles—particularly in the comprehensive "defense of homeland" scenario suggested by President Reagan in his March 23 address.

The President never specified what technology he thought might be used to defend the U.S. public in an all-out missile attack. Some military experts call for three lines of defense: a set of satellites bearing conventional weapons orbiting over the Soviet Union to knock out missiles during their boost phase; another set of satellites with laser weapons to fire at warheards that sneak past the first defense; and ground-based U.S. rockets to mop up any remaining warheads.

The laser portion of such a defense theoretically could be any of a number of devices now under study. Chemical lasers, pumped by the combustion of hydrogen and fluorine, have received the most attention. The DOD and the U.S. Department of Energy are exploring other options for directed-energy weapons, including free-electron lasers and particle beams. Particle-beam weapons for space have been under study at the Los Alamos (N.M.) National Laboratory since 1974. Another possibility is the nuclear-bomb-pumped X-ray laser espoused by Edward Teller; it is reportedly undergoing successful testing at the Lawrence Livermore Laboratory in California.

General Richard Henry, recently retired commander of the Air Force Space Division, Los Angeles, Calif., said "A laser that is capable of destroying a ballistic missile warhead would require a spacecraft weighing several tons at low altitude and a command and control system that would boggle the imagination. In theory it could be done, but we would need a breakthrough."

Breakthroughs can happen, noted Gen. Henry, recalling a similar situation in 1953, when the United States was trying to build an intercontinental ballistic missile. "We knew in theory we could do it, but we didn't know how," he said, "because in those days our bombs weighed 10 000 pounds." The breakthrough was inventing a nuclear weapon "that weighed an order of magnitude less." President Reagan's initiative to begin research on antiballistic missile systems, Gen. Henry said, makes sense as a precursor to a similar breakthrough in laser or beam weapons.

Beam weapons viewed as vulnerable

Critics of space laser and beam weapons point out, however, that even if a device could be built, it would be as vulnerable to attack as any satellite. And, they say, the weapon might easily be tricked and its power exhausted if an enemy launched fake missiles first or if the missiles were protected with heat shields. Such strategies would cost far less than beam weapons.

Mr. Williamson, the former assistant to the administrator of NASA, called a missile-defense strategy unrealistic. Even if a U.S. antimissile system turned out to be 95-percent effective, he said, 9 megatons of Soviet nuclear explosives could still leak through. A 13-kiloton weapon, he noted, left 105 000 people dead at Hiroshima and Nagasaki.

President Reagan did not say the United States should definitely build a missile defense, but he hopes that someday the U.S. technological genius may find an alternative to the policy of mutual assured destruction. "Wouldn't it be better," he asked, "to save lives rather than avenge them?"

Gen. Hartinger argued, "Since World War II we've had only offense, no defense. I think to develop a defense against ballistic missiles has to promote stability and balance in the world."

Dr. Logsdon does not agree: "I think it would be the most destabilizing thing you could think of. If you were someone who felt threatened by your opponent and you saw him building walls around himself, you'd make sure that if you were ever going to attack, you'd do it before the walls were complete."

Given the growing accuracy and megatonnage of each superpower's ICBMs—for example, Cheyenne Mountain could no longer survive a direct Soviet nuclear hit—both nations may be moving toward a "first strike" posture, some weapons critics say. According to this scenario, if a superpower launched the first strike, it would suffer far fewer losses than its opponent, which might not be able to retaliate with full force.

"This creates an unstable situation, for it creates an incredible

incentive to go first," said John Pike, staff assistant for space policy at the Federation of American Scientists, Washington, D.C. He believes the incentive would only increase if the superpowers had laser missile defenses. "My impression," he explained, "is that a laser would not be effective against a well-coordinated first strike but might be a highly effective defense against a poorly coordinated retaliation."

World stability can only be promoted, said Gen. Hartinger, "if we reduce both nuclear arsenals to an equitable, verifiable, more rational level, and then bring defense into the game."

The United States will be forced in the next five years to make some key policy decisions about the future of its military involvement in space. Congress will vote on whether to procure the new antisatellite device, a major step in commitment to the weapon. The Pentagon will decide whether to go ahead with the demonstration of a space laser. Congress will vote on four resolutions supporting the banning of weapons from space, and the President will decide whether to seek negotiations with the Soviet Union over space weapons. ◆

INTERNATIONALIZATION: HARMONY OR TENSION?

When President John F. Kennedy decided in 1961 to put the United States ahead of the Soviet Union in space technology by sending men to the moon, telephones were virtually nonexistent in Indonesia. But now the situation for both Indonesia and the United States has changed.

Last June the U.S. Space Shuttle released from its cargo bay the third Indonesian telecommunications satellite, Palapa-B [Fig. 1]. Far from having no telephones, Indonesia, a 3000-mile string of islands along the equator in the Indian Ocean, plans to lease circuits on the satellites to neighboring countries for regional telephone service and television broadcasting, in addition to using the satellite for its domestic needs. And far from exploiting space solely for scientific reasons, the U.S. National Aeronautics and Space Administration launched Palapa-B for a fee, and it had to bid for the launch contract against the European Space Agency (ESA).

Space programs are no longer solely a flexing of technological muscle by the United States and the Soviet Union. Today satellites and other space developments are important economically and militarily for many nations, and this dependence has fostered both greater cooperation and competition between nations than existed in the pioneer years in space.

NASA ended the Apollo moon program a decade ago and is gearing for competition from other countries that have developed the capability to launch satellites. Intelsat, the internationally owned corporation that manages a world telecommunications network, has over 100 participating countries, but its dominance began to erode when NASA launched Palapa-B and the ESA launched the European regional communications satellite last June on its Ariane booster. In addition, several regional and domestic satellite communications systems are being planned for the next five years by India, Australia, and Arab and Latin American countries.

For some developed countries, space technology has become an often crucial aspect of military activity and an expanding industry. For developing countries, satellite communication is a way to leapfrog the costly, slow development of telephone lines and microwave transmission stations. Remote-sensing satellites provide information about countrysides that no other affordable method can give, and direct-broadcast satellites can open the way for inexpensive television reception in remote regions.

The importance of space technology to the well-being of nations has made it the subject of debate at the United Nations. Those debates often concern the fears of the developing world of exploitation by the industrial powers, upon whom they depend for the technology. They want treaties that guarantee them the right to control both what is broadcast into their countries and the dissemination of information gathered about their lands by remote-sensing satellites. They argue that the geosynchronous location of communications satellites is a precious resource that should be divided equitably between all countries, regardless of ability to use it. Several equatorial countries even claim sovereignty over the geosynchronous arc above their lands.

Fred Guterl Associate Editor

Space progress as a symbol

In the early 1960s, space technology was important primarily to the United States and the Soviet Union, the two industrial and military superpowers caught up in the cold war, where success was measured in terms of international prestige and stockpiles of missiles able to launch nuclear warheads. Since other countries also recognized the potential of using space, the two superpowers vied for world leadership. The United States poured billions of dollars into the booster and satellite technologies, among others. The manned space program captured public imagination and created an aura of U.S. technological supremacy.

As the politics of the cold war warmed during the detente of

(c) 1983 IEEE. Reprinted with permission, from IEEE SPECTRUM, Vol. 20, No. 9, pp. 26-98, September 1983.

the 1970s, space technology again provided the symbols. In 1975 a U.S. Apollo spacecraft and a USSR Soyuz spacecraft docked in space. Television cameras transmitted to the earth images of U.S. astronauts and Soviet cosmonauts shaking hands in space.

But the reluctance of both the Soviet Union and the United States to reveal technological information during the Apollo–Soyuz project underscored the limitations of cooperation in space. Both countries designed the mission to require little exchange of technology. Only the interface between the two spacecraft required an exchange of blueprints: the Soviet design was used.

The Apollo–Soyuz project somewhat improved cooperation between the two superpowers, although not as much as NASA had hoped, said Marcia Smith, a specialist in space and telecommunications at the Library of Congress in Washington, D.C.

Europe begins to compete

The countries now in the European Space Agency began negotiations in 1961 for a cooperative European effort to develop a rocket-launching capability and a space science program. The ESA effort has produced the Ariane booster and also the Spacelab, which is to be launched next month in NASA's space shuttle [see "Spacelab: The biggest joint ESA–NASA effort"].

The European effort illustrates how several nations, often with conflicting priorities in space, can work out compromises and pool their resources. The French, for example, were adamant about developing booster technology, while the West Germans and the British wanted to stress payload systems and manned space activities. Both goals eventually were met in the largely French-backed Ariane booster and the largely German-backed Spacelab. Officials of France's space program persuaded their European counterparts to contribute to the Ariane by arguing that the United States would otherwise continue to control Europe's access to space. The German initiative to develop a manned program led to involvement in the Spacelab, which entailed cooperating with NASA on the space shuttle program.

In the beginning of European involvement in space, French space officials stressed the value of space technology to national industrial health. The French policy under President Charles de Gaulle was to be staunchly independent, and that included the independence of the French space program from NASA. Independence meant the capability to launch satellites: as long as NASA had a monopoly on booster technology, the French feared the possibility of NASA vetoing a French mission.

The European Launcher Development Organization (ELDO) was formed in 1964, mainly through French and British efforts. It had the backing of military leaders who believed that booster technology was essential to an independent European military force. It also had the support of European aerospace companies and defense contractors, who had much to gain from expensive contracts.

That same year, the European Space Research Organization (ESRO) was formed, by contrast, mainly to unify in Europe what had been fragmented cooperative efforts with NASA in space science, and also to allow nations without space programs to participate. It had the backing of scientists who felt that Europe did not have the resources to compete with NASA in booster technology and that money would be better spent developing scientific experiments. They also felt that Europe had no reason to fear a NASA veto of launches for scientific projects, since the U.S. space agency had always been cooperative in launching European experiments.

A dispute over the launching of an applications payload acted as a catalyst in the formation of the ESA and the decisions to develop the Ariane booster and Spacelab. Officials of the French space program asked NASA to launch the Franco–German Symphonie satellite, which they said would be used for domestic telecommunications. But then some French officials made statements indicating that the satellite was to be for commercial international communications. At the time, however, the Intelsat agreements, to which France was a party, referred to Intelsat as the single global communications system. The U.S. State Department interpreted the wording to mean that no member nation could deploy a commercial international satellite system.

On learning of the French official's statements, the U.S. State Department asked the French government to sign a pledge that its satellites would not be used for commercial international com-

Spacelab: the biggest joint ESA–NASA effort

The Spacelab mission scheduled for launching Oct. 28 in the U.S. Space Shuttle is the fruit of the most extensive cooperative effort between the European Space Agency and the U.S. National Aeronautics and Space Administration. The billion-dollar program has weathered some difficulties due to delays in development and to an early misconception that flights would be more frequent than they are now being planned. Nevertheless, it will soon give scientists new information on the earth's atmosphere, materials processing, astronomy, and medicine, to name just a few areas.

The project began in 1973 when NASA and the European Scientific Research Organization, a forerunner of the ESA, agreed that the European organization would be responsible for designing and building the Spacelab, and that NASA would provide the shuttle to launch it. The orbiting laboratory, designed to fit inside the shuttle's cargo bay, can be configured for manned or unmanned operation, as well as for holding instruments of widely varying sizes and requirements. (Although the Spacelab project is moving ahead successfully, officials of the French space program said Spacelab might not have been the best choice the ESA could have made in the early 1970s, when NASA offered the agency a choice between the Spacelab and a space tug. As envisioned, the tug would have ridden in the shuttle's cargo bay and then flown from the shuttle's low orbit to a geostationary orbit 22 000 miles high to service satellites.)

On its first mission, Spacelab will carry two payload specialists—one from Europe and the other from the United States—and 37 experiments, mostly European. Afterward, NASA will become the owner of Spacelab, and the ESA will have achieved its first successful manned space flight.

The frequency of Spacelab launchings in general has given rise to the dissatisfaction of French space officials. Ten years ago, it was hoped that Spacelab launches would occur more often than is now anticipated. Hubert Curien, president of the Centre National d'Etudes Spatiales, the French space agency, said: "People didn't realize it would be very difficult to get a ticket to fly in Spacelab—it will be the same for a U.S. citizen and a European."

The high cost of Spacelab launches has been a surprise to NASA and ESA officials alike. Mr. Curien's assessment of the problems of access to Spacelab is fair, according to Arnold Frutkin, formerly head of international affairs for NASA, but they are not unique to Spacelab. For other programs, including the U.S. Space Shuttle and ESA's Ariane, schedules and cost estimates have deviated from plans, thus delaying access, he said.

—*F.G.*

This October, the European Spacelab will ride in the U.S. Space Shuttle's cargo bay, configured with a long pressurized cabin where two scientists will work (top right). In other missions, Spacelab can be configured with a smaller cabin and instruments for earth observation (right), or completely unmanned with instruments for solar physics (far right).

munications. A debate ensued. Officials of the French space program contended that NASA was refusing to launch the satellite, which aroused feelings in Europe that space programs would be subject to NASA's whims unless European booster technology became a high priority.

Arnold Frutkin, who at the time was the head of international affairs for NASA, said the space agency did not refuse to launch the satellite, but rather set the condition that the satellite could not be used for commercial international communications. In fact, he said he felt it was excessive for the State Department to demand that the French sign a pledge. Moreover, "we really controlled the situation," he noted. "If the French had gone ahead and violated the Intelsat agreement, then we could have refused to launch another French satellite, and they couldn't have kept the system going with only one."

Two Symphonie satellites eventually were launched by NASA, but only after the nations belonging to ESRO and ELDO agreed in 1973 on a plan to combine the two organizations into the European Space Agency and to begin development on the Ariane booster, the Spacelab, and a maritime communications satellite.

Europe also created a single voice for articulating its objectives in space. By the early 1970s the rigid guidelines for participation in ESRO and ELDO had begun to seem obsolete. Under these rules, whenever either organization undertook a project, participation by all member nations was mandatory. The money each country contributed to the organizations was based on the size of its gross national product. As space technology became increasingly important to each country, the ESRO convention was extended to include applications projects in addition to the scientific projects, and some members began to consider producing and using their own satellites as an important element in their future industry.

I. European cooperation: who gives what (percent)

Country	To ESA (in 1983)	To Ariane (since 1973)	To Spacelab (since 1973)
France	28	64	10
West Germany	22	20	56
Great Britain	18	3	7
Italy	14	2	18
Others*	20	11	12

*Includes the Netherlands, Belgium, Spain, Switzerland, Sweden, Denmark, and Ireland and the non-ESA members Canada, Austria, and Norway, which each contribute 5 percent or less.

The ESA convention drafted in 1975 infused flexibility into joint ventures. It stated that involvement in applications programs is optional, although all members still must contribute equally to scientific efforts. Under its terms, each participating country can also choose how much money it wants to contribute to each program [see Table I]. Currently, France contributes slightly over 60 percent of the funds to develop Ariane, for which about $650 million has been spent since the project's inception. West Germany, in line with its emphasis on payload programs, contributes over 50 percent of the Spacelab budget, which totals about $900 million since the beginning of the project.

Developing countries seek access to space

Meanwhile the developing countries are calling on the developed countries to provide better access to sophisticated space technology. And the technology has become inexpensive enough to encourage many countries to buy their own satellites or form satellite consortia with neighboring countries for regional communications. Owning a satellite bestows far more prestige on a nation than does leasing services from Intelsat, as these countries are discovering.

This upsurge of interest in satellites reflects their usefulness in allowing a country to bypass more expensive communications technology. Intelsat has been besieged with developing countries' requests for transponders for domestic telephone-service use. The number of developing countries leasing circuits from Intelsat

for domestic telephones has grown from two in 1974 to 24 in 1983; Intelsat expects that number to reach 54 by 1985 [Fig. 2].

In the past, Intelsat has offered such service only when it has had satellite capacity left unused from heavily trafficked international communication routes. Thus, demand has been exceeding supply, and some developing countries are making plans for buying their own satellites for regional and domestic communications.

For example, Indonesia, the first developing country to own communications satellites, decided to buy a satellite from the United States and have NASA launch it because "our demands are too big for Intelsat," said R. Sunaryo, head of the Indonesian National Institute of Aerospace and Space.

When formed in 1964, Intelsat had 16 participating countries, each owning a share based on its use of the network; however, the United States, as a major user, owned 63 percent. "It was a *de facto* U.S. monopoly, and it was forced on the rest of the world because the United States had all the technology and the Europeans wanted it," according to John Logsdon, who holds the Chair in Space History at the National Air and Space Museum, Washington, D.C.

Modifications to the Intelsat agreements occurred from 1969 to 1971, when the growing participation of developing countries led to a policy more conducive to equal representation of all members. Most of Intelsat's business still goes to U.S. contractors, and over 50 percent of its staff are U.S. citizens, but the United States owns only 24 percent of the corporation. Though still the largest single share, new countries entering the organization promise to dilute U.S. ownership further. An article in the new convention clarified the conditions under which Intelsat members could approve other international commercial satellite systems. It stated that no other satellite system could be allowed unless it could be coordinated technically with the Intelsat network and it could be proved that it would not cause Intelsat "significant economic harm."

Some experts say Intelsat will have to adapt in coming years as more regional telecommunications systems spring up. "In five years, Intelsat will be a far different organization from what it is now," said Gordon Law, a consultant to the U.S. Congress Office of Technology in Washington, D.C.

The Indonesian, European, and Arab satellite networks have all been approved by Intelsat. In line with the demand for domestic service, Intelsat is considering plans to service more remote areas. "We will adapt to the new environment," said Joseph Pelton, executive assistant to the director of Intelsat, "by offering more kinds of service, by using smaller earth terminals

Space cooperation is sometimes a victim of budget cuts

Even the best international agreements for cooperation in space sometimes go awry for reasons unrelated to the interests of the agencies involved. One example is the International Solar Polar Mission.

This U.S.-European project was set up by the National Aeronautics and Space Administration and the European Space Agency in 1979. Two satellites—one made by NASA and the other made by the ESA—were to be launched by the U.S. Space Shuttle, fly past Jupiter, and then pass close to the sun on elliptical orbits. One satellite was to pass over the north pole of the sun, the other over the south pole. This way, scientists could use the two satellites with identical instruments to get a stereoscopic view of the sun.

Planning was proceeding nicely until NASA presented its fiscal year 1982 budget to the U.S. Office of Management and the Budget. The Reagan administration cut the project.

But the project survived, although only one satellite—the one made by the ESA—will make the trip past the sun. NASA will still provide a free launch and the tracking stations on the ground. All of the experiments originally planned will be carried out, though on one rather than two satellites.

One former NASA official said the Reagan administration was young, inexperienced, and understaffed and had simply made a mistake. Another said that NASA had submitted the solar-polar mission as a candidate to be cut in a gamble that the budget office would restore the program because it entailed a commitment to the ESA. Others say that the program would have been cut anyway because the Reagan administration proposed severe budget cuts to almost all parts of the Government that year.

—*F.G.*

for rural and business communications, and by improving our technology."

Developing versus developed power

Although the developing nations want space technologies and see them as essential to rapid development, they also want to avoid dependence on the more technologically advanced nations, and they want to place limits—through UN treaties and the pressure of world opinion—on how much those nations can exploit the developing countries.

At the Unispace '82 conference in Vienna, developing nations expressed concern over three key technologies: remote sensing, access to geostationary orbits, and direct-broadcast satellites.

Geostationary orbit, some 22 000 miles above the equator, is attractive for communications satellites because there they orbit at the same rate as the earth revolves and thus remain in a fixed location in relation to the earth's surface. Receiving and transmitting stations on the ground need only point in a single direction all the time. But the arc of these orbits is becoming overcrowded. Despite assurance from the United States and other developed countries that technological advances will alleviate the overcrowding, the developing countries fear being shut out of the telecommunications business. Unless curtailed by treaty, they contend, the industrial nations will use up all of the available slots before the developing nations can build their own satellites.

In 1977, the countries of the UN International Telecommunications Union, which includes almost all UN members, met at the World Administrative Radio Conference (WARC) in Geneva to divide the equatorial orbital arc for the K-band broadcast frequency used for direct-broadcast satellites. Although no such satellites were being used then by any nation, each ITU country, except those in North or South America, was assigned its own slot, regardless of whether or not it had plans for using the slot. The Americas decided among themselves last July in the Regional Administrative Radio Conference in Geneva how to divide the remaining slots.

These agreements on orbital slots are similar to the Law of the Seas Treaty, in that they would create a mechanism for dividing a limited natural resource among all nations, whether or not they made any investment to obtain or use the resource, according to S. Neil Hosenball, chief counsel for NASA. The 1982 Law of the Seas Treaty, which the United States and a handful of other industrialized countries refused to sign, created an international enterprise through which any profits from mining deep under the oceans would be distributed equally to the developing countries. The prior assignment of orbital slots may make it necessary for developed countries that want to expand satellite capacity beyond their allotments to rent the orbital slots from developing or neighboring countries. Whether or not slots from one region could be leased to serve another region is unresolved.

Other WARC meetings are planned for 1985 and 1988, in which the assigning of orbital slots for all types of communications will be discussed. Currently, the K band (14 gigahertz on the up link, 11 on the down link) is not used extensively, and thus the assignment of orbital slots corresponding to the K band occurred while the slots still were available. But the C band (6/4 GHz) is becoming crowded. Developing countries want the developed nations to switch to higher-frequency bands for communication and leave more of the C band, which requires less expensive communications technology, for them. Currently, the C band accounts for about 90 percent of all communications.

The United States disagrees with the other countries of North and South America on whether orbital overcrowding will keep developing countries out of the telecommunications business. U.S. critics of the ITU agreements said that technological advances will make it cheaper to pack more communications channels into a smaller bandwidth, as well as to construct space platforms to alleviate orbital crowding.

Communications technology has a history of using higher fre-

II. Selected future projects of non-U.S. space powers

CANADA

1988 Mobile-communications satellite (MSAT), for mobile and remote users.

1990 Synthetic-aperture radar satellite (Radarsat) for remote sensing through cloud cover and at night.

CHINA

1984 CZ-3 launching vehicle capable of putting payloads into geostationary or sun-synchronous orbit. Communications satellite, STW-2, and meteorological satellite to be deployed by CZ-3.

EUROPEAN SPACE AGENCY

1984 Maritime communications satellite, Marecs-B2, to be deployed by Ariane.

1985 Halley's Comet observatory satellite, Giotto, to be deployed by Ariane.

1988 Large communications satellite, Olympus (formerly called LSAT), to be deployed by Ariane. International Solar Polar Mission (ISPM) satellite and space telescope with ESA-built faint-object camera to be deployed by shuttle.

1987 European remote-sensing satellite (ERS-1) to be deployed by Ariane.

1988 Astronomical surveying satellite, Hipparcos, to be deployed by Ariane.

1988 to 1990 Infrared space observatory (ISO).

FRANCE

1-4B Remote-sensing satellite, SPOT; communications satellite, Telecom-1; and direct-broadcast television satellite, TDF-1, to be deployed by Ariane.

1986 Ariane 4 series launching vehicles to be deployed.

GREAT BRITAIN

1985 Military communications satellite, Skynet IV, to be deployed by shuttle.

1988 Olympus, primarily British-built, and direct-broadcast television satellite, Unisat-1, to be deployed by Ariane.

INDIA

1984 Indian remote-sensing (IRS) satellite to be deployed by USSR. Indian cosmonaut to join Soviet team on Salyut 7 space station.

1986 to 1987 Polar satellite launching vehicle (PSLV), capable of putting 1000-kilogram payload into sun-synchronous orbit, to be deployed.

Indian communications satellite (Insat) to be deployed by shuttle.

JAPAN

1984 Communications satellite, Sakura-2A, and geostationary meteorological satellite (GMS-3), to be deployed by Japanese N-series boosters.

1986 Halley's Comet observatory satellite, Planet-A, and heliocentric sun observatory satellite, MS-T5.

1986 to 1987 Marine-observation satellite (MOS).

1988 to 1988 Earth-resources satellite.

USSR

1988 Venus–Halley's Comet spacecraft, joint project with France, will drop probe onto Venus, rendezvous with comet in 1986.

1986 to 1987 Deployment of space station to succeed Salyut.

Tentative plans Construction of space shuttle. Manned mission to Mars.

WEST GERMANY

1985 U.S. Space Shuttle–Spacelab mission, D-1, devoted to German experiments.

1987 X-ray telescope satellite, Roast, joint project with Great Britain and the United States, and Jupiter orbiter-probe, Galileo, joint project with the United States, to be deployed by shuttle.

quencies to fit more signals into a crowded bandwidth, said John McLucas, president of Comsat World Systems. "You will find you can reuse existing frequencies more often than you thought you could, narrow the spot size of beams, stack satellites closer together, and get more mileage out of the existing spectrum," he noted.

Developing nations are worried that using the higher frequencies will require money and expertise which they lack. For example, Dr. Sunaryo, head of the Indonesian space program, told *Spectrum* he is concerned that developed countries will overcrowd the lower-frequency orbital slots, forcing Indonesia to use the more sophisticated—and expensive—technology for the higher-frequency slots.

Aside from the greater expense, developing countries also have expressed concern that sophisticated technology is difficult to maintain in countries such as Indonesia, which is largely agricultural. "We don't have the manpower for all the systems we'd like to have," said Mr. Law, the Office of Technology Assessment consultant in Washington, D.C. "If we don't, with our educational system, what chance do developing countries have?"

In proposing solutions to the overcrowding problem, people in the United States tend to think of technological development in terms of what is suitable for their own country, noted Ray Williamson, a project director at OTA. For example, "One engineer painted a whole scenario of how fiber optics would force down the price of satellites, except that he didn't realize that fiber optics is not an option for many developing countries because it doesn't fit into their infrastructure," he said.

Earth satellites at issue

Another area of dissent between developing and developed nations involves how best to share the fruits of space applications. The Landsat satellites, for example, have been providing information about countries that often cannot be obtained as cheaply in any other way. Current U.S. policy is to sell Landsat data without discrimination to anyone who wants them—an equitable policy, except that developing countries say they do not have the capabilities to process or interpret the data. They fear exploitation by organizations that have the computers and expertise to do the job. For example, commodities traders might use early estimates of foreign crop yields to manipulate markets. For this reason, a group of 77 developing countries at Unispace questioned the right of the United States to disseminate Landsat data about one country to other countries.

The National Oceanic and Atmospheric Administration, which is currently responsible for Landsat, offers the information at a set, subsidized rate to all nations. In addition, the U.S. Advanced Information Development Program teaches people in Kenya, Upper Volta, and Thailand how to use Landsat data.

As for direct-broadcast satellites, with their potential not only for educational television, but also advertising and commercial television, the Soviet-bloc countries fear propaganda from the West, the French fear a degradation of quality in programming, and Indonesia fears its people will learn to desire luxuries they cannot afford.

Many nations want a UN treaty requiring a foreign entity, such as a broadcasting network, to obtain the permission of a country before signals from a direct-broadcast satellite service can be received in that country. The Soviet Union has voiced particular concern over this issue. The General Assembly of the UN adopted a resolution, in December 1982, calling for "consultation and agreement" if one country's broadcasts will spill over unintentionally into another's, but the resolution is not legally binding.

Outlook for cooperation

The prospects for future cooperative ventures among the developed countries appear bright [see Table II]. NASA is planning joint projects with Canada, several European countries, Japan, and others. France is planning joint projects with the Soviet Union and is cooperating with India on its space program. The

Great Britain	121 million
Canada	112 million
India	97 million
Italy	29 million
China	not available

* Rough estimate, including both military and civilian expenditures

[R] International cooperation in communications takes place mainly through the Intelsat and Intersputnik networks. Regional and domestic systems, however, are springing up to supplement the Intelsat service. The map indicates those governments who own non-communications satellites and launchers; the table (left) further differentiates among these wealthier space powers. (Note: the United States was not counted among those countries with government-owned systems, because U.S. communication systems are primarily privately owned.)

Infrared Astronomy Satellite, a U.S.–British–Dutch observatory launched last January, is an example of a successful joint mission. It has discovered comets and other phenomena by detecting their infrared radiation. Last month the satellite uncovered the first substantial evidence of a planetary system other than our own—orbiting Vega, a star 26 light years from the earth.

Some diplomatic wrinkles will need ironing out for future projects, however. For example, in projects with NASA, France wants more input at the planning stages than it had in the Spacelab project. Hubert Curien, president of the Centre National d'Etudes Spatiales, the French national space agency, said that NASA approached Europe long after its post-Apollo plans had solidified. "It's not the same being invited to a mission and being a father of a mission," he said. "But from time to time, it would be rewarding for French or European scientists to be involved from the very beginning in the definition of a mission."

Mr. Beggs, the NASA administrator, is sympathetic to Mr. Curien's view. "We have in most cases waited until we had a program committed . . . before we invited them to take part," he conceded. "But in the case of the [proposed] space station, we invited the Europeans, the Canadians, and the Japanese to participate in our studies."

Although cooperation between the United States and the Soviet Union is at a low, the two superpowers have been exchanging data. "The Soviets have given us some biological and physiological data on their manned flights that have been extremely useful in assessing the effect of long-duration weightlessness in flights," said Mr. Beggs. "Also, we're assisting France in designing an instrument on its upcoming Venus mission," he added. "What the Soviets don't tell us is what they're doing out there, the specific experiments, whether they are involved in any specific work that is related to anything we have in mind for the future."

In the United Nations, the military presence in space promises

to remain at the forefront of debate. Military involvement in space is the most threatening and important issue concerning future international cooperation, especially with the developing countries, according to Marvin Robinson, who retired last May as head of the UN outer-space division.

Nevertheless, the military issue will remain. The U.S. delegation to Unispace '82 almost walked out of the conference because many developing countries wanted to discuss the threat of militarization on international affairs, according to a member of the U.S. delegation. The U.S. policy is to debate the issue only in arms-limitation talks, to prevent the technical issues concerning space from being eclipsed by the military issues at conferences such as Unispace. ◆

COMMERCIALIZATION: HIGH TIME FOR PROFITS?

From the outset, proponents of space exploration have argued that it is justified because of its enhancement of national security, contribution to basic scientific knowledge, and potential for economic gain. Without reconnaisance satellites, they say, international tensions would mount. Scientists point to multitudes of discoveries about the universe, the solar system, the moon, the earth, and the human body that have resulted from space programs. But outside of communications, little economic gain has been realized directly from the first 25 years of space activity.

That situation is changing. The United States government monopoly on space launching is ending, and companies like General Dynamics Convair Division in San Diego, Calif., and Federal Express, along with new ventures, such as Space Services Inc. of Houston, Texas, and Starstruck Inc. of Redwood City, Calif., are preparing to compete for a share of the business. Arianespace in France is already marketing a rocket. Estimates by these potential competitors indicate that commercial space-launching revenues could total $6 billion through 1991.

The U.S. Government has also indicated that it intends to stop making data from remote-sensing satellites available for nominal fees, and companies like Spot-Image SA in France, American Science Technology Corp., and Terremar Inc. are preparing to send up their own satellites to gather data for map making, crop monitoring, and mineral-resource assessment and to sell that information for a profit.

Tekla S. Perry Associate Editor

Space Services Inc.

McDonnell Douglas Corp. and Johnson & Johnson have demonstrated in space a manufacturing process for pharmaceuticals that they hope will be ready to make drugs for clinical testing in 1985. And other companies are planning the manufacture of gallium arsenide crystals and alloyed metals in space in the late 1980s.

A need for high finances and low risk

This spurt of interest in commercial space activity seems slow in coming. Remote-sensing satellites—operated in space before communications satellites were even tested in geosynchronous orbit—and launching technology have been mature for years, yet the commercial sector stayed out of these businesses while it put the communications satellite business into the black in 1968 and then expanded it to its current annual revenues of $2.5 billion. If space as a high-technology industry has a potential for big payoffs, why have entrepreneurs and venture capitalists shunned it for so long?

For one thing, space ventures have much higher capital needs than other high-technology industries. "You don't come in as a financing institution and take a flier," said Jerry Simonoff, vice president of Citicorp Industrial Credit Inc. of Harrison, N.Y., and few entrepreneurs can afford to finance such expensive endeavors out of their own pockets.

Difficulty in attracting investors, however, is not the only reason not all sectors of the space business have been booming. The answer lies in the infrastructures surrounding the technologies. As a train engine cannot operate profitably unless it is integrated with a rail system and can reach its customers at convenient stations, space ventures need to be able to deliver their products to an established market.

Communications, as an industry, has existed for 100 years, nationally and internationally, going back to the telegraph. It has over the years developed a price structure and a network of users. Communications satellites, as a new technology, have been able to plug into that network, increasing its capabilities and decreasing costs without changing much at the customer's end. The industry has also consolidated into a few very large private companies and government concerns serving a defined market.

Remote sensing, as an industry, has also been in existence for some time. People throughout the country have come to rely on weather data supplied by U.S. government satellites. This market is aggregated

[1] In September 1982, the expendable launch vehicle Conestoga was launched from a private ranch on Matagorda Island, Texas, by Space Services Inc. of Houston. Though only a test launch, it marked the entry of the private sector into the space launch business. SSI will follow this test with a commercial launch in 1985.

and large. However, it is not a true market because the Government has been supplying the weather data free, as a public service, and it would be difficult to make users now pay for this information.

Another potential market for remote-sensing satellites is aerial surveying to assess mineral resources, check timber growth, or improve map making. The market has a well-defined price structure, but it is very difficult to plug into. When communications satellites were developed, the few but wealthy potential customers could guarantee a market in themselves. Already buying remote-sensed data from local pilots are many small potential users who would be difficult to aggregate into a satellite market.

The barrier to launching services has been slightly different. The communications companies made a clear market and facilities such as launcher production lines and launching pads have multiplied as space activity has grown. These facilities, however, have not been available for commercial use: the Government controlled them and had a monopoly on space-rocket launching until the European Space Agency (ESA) developed its own launcher, the Ariane, and established a commercial company to market it worldwide. Now even the Soviets have indicated an interest in the commercial launch business, entering the Proton rocket in the competition for the business, and private U.S. companies are getting ready to compete.

Billions in launching revenues foreseen

Launching services will be needed for approximately 245 commercial satellites between 1986 and 1995, with potential revenue of $10 billion over this period, predicted William F. Rector III, vice president of space programs for General Dynamics. There is a potential market for 180 satellites that can be launched at an average of $30 million per satellite between 1985 and 1991, according to the French company Arianespace.

General Dynamics and Arianespace are only two of the many private companies that may compete with the National Aeronautics and Space Administration (NASA) for the business of launching satellites into orbit over the next few years. The projections of these two companies are based on proposed communications satellites; the market may be bigger than predicted if other commercial space ventures take off.

Arianespace, the first commercial competitor to the U.S. government launching services, was incorporated in 1980 as a private company in France. It is partly owned by the French national space agency, but the majority of the company is held by aerospace companies and banks throughout Europe. Starting next year, Arianespace will produce, finance, market, and launch Ariane expendable launching vehicles.

With the U.S. government's monopoly broken, President Ronald Reagan announced this May that the U.S. government was giving up its control of the launching of expendable rockets and that those companies that had been manufacturing the rockets or other private companies could buy parts and Government-owned plans for the launchers at cost and use Government launching pads and personnel for a fee. The manufacturers had been testifying in Washington for months in favor of such a policy. They were careful to present their pro-

Private launchings face regulatory unknown

Now that Space Services Inc. of Houston, Texas, has proved with a suborbital test launching that getting a satellite into space does not require government personnel or launching facilities, and other companies are proposing independent launchings, new regulatory methods must be found if governments are to keep control of space activity. Space Services had to cross uncharted regulatory territory that could easily have delayed or canceled its test launching from Matagorda Island off Texas, in 1982. (An earlier attempt by the company to launch a rocket in 1981 failed when the rocket blew up on the launching platform.)

Charles Chafer, Space Service's vice president of government affairs, describes the company's experience:

"For our first test launch, regulation was minimal, because no one had thought much about it. The next time we planned a test launch there was an interagency group put together to determine a regulatory scheme. It decided we needed FCC clearance, so we got an experimental radio license for the command-destruct telemetry. From the Federal Aviation Administration we had to get an exemption.

"The exemption required two Federal Register notices with public comments. We got an export license from the State Department. It's hard to see what we exported, but they said that under the 1967 treaty they had responsibility to supervise our activities and they needed some mechanism to approve us, so they decided on an export license under the munitions control act. We got that the day before the launch. "We also got a gun dealer's license from the Bureau of Alcoholic Beverages and Firearms, because we used artillery rockets to calibrate our radar. Because we purchased the motor from NASA, it imposed a liability insurance requirement on us.

"Then we had a series of informal arrangements with the Coast Guard and the Navy, because we were launching near an air-training center, and with Norad. Norad said it didn't have the authority to make us cooperate with it, but would we please keep a line into them so we wouldn't hit any low-flying satellites. We weren't ever officially informed by anybody about all the things we had to do."

None of these regulatory bodies, however, gave the Space Services project any kind of technical review. The Government is leaving that to the insurance industry. For the company's test project, the National Aeronautics and Space Administration demanded that Space Services obtain liability insurance. Once the company is ready to operate commercially, the customers will require a guarantee, that they will get their money back if for example—as happened on a recent Ariane launching—the launcher fails and dumps its payload into the ocean.

Stated Brian Hughes, a staff member of the U.S. Aircraft Insurance Group, a consortium of 15 major U.S. insurance companies and the first insurer to offer space coverage with a policy on the 1965 Earlybird communications satellite, "We will insure anything flying, with different premiums, depending on the history of the vehicle." Under that guideline, the expendable launchers being commercialized now in the United States, all with excellent records, will qualify for the lowest insurance rates; Ariane, with a shorter history and a greater percentage of failures, will qualify for higher rates; and Space Service's newest launcher for slightly higher. The judgment of the insurers, however, is not perfect—from 1978 to 1982, Mr. Hughes said, $1.6 billion in damage insurance was purchased for space ventures, with the insurers receiving, after commissions, $100 million in premiums and paying losses of $184 million.

The U.S. Government says that the Space Services launching was a learning process for the Federal agencies, and now an interagency group is trying to figure out what the licensing process should be. One agency noticeably missing from the list of permission granters is NASA, and the space agency's administrator, James Beggs, said that is the way it should be.

"I don't want NASA doing it," he said. "NASA is not in the regulation business: we are a research and development agency. Some other agency should be doing that. Since a number of different agencies and departments are involved, there should be a single point of coordination. Our hope is to find some agency that will take on that chore." —*T.S.P.*

Space technology spins off benefits

More than 3500 inventions that can be applied on Earth are available for licensing as a result of spinoffs from the U.S. space program. Under the 1958 legislation that created the National Aeronautics and Space Administration, the agency is required to disseminate to the public any technology it develops. The methods it uses include a quarterly publication listing new technologies available for transfer, various applications centers at which NASA engineers are available to help industry apply space technology, a computerized information-retrieval system, and programs that allow representatives of industry to visit NASA facilities.

These efforts have transferred much technology developed for use in space to the private sector, where it has found new commercial uses. As an example of how the process works, Ronald Philips, NASA's director of technology use and industry affairs, described a technique picked up by John Deere & Co. of Moline, Ill.

"John Deere builds heavy equipment," he noted. "One of the continuous problems was that where the tracks on their tracked vehicles connect, they wear out easily and must be replaced often. On a visit to our Langley [Hampton, Va.] and Lewis [Cleveland, Ohio] research centers, at which our scientists and engineers give presentations about ongoing projects, Deere discovered a technology that, developed by discussions with people in our laboratories and reading of our publications, let the company make a new device for the bonding of tracks together. It has a much longer life and provides significant savings for customers."

Other examples of successful technology transfer include:

- Programmable implantable medication systems that dispense measured amounts of drugs, like insulin. These arose from technology developed for the Viking missions to Mars, in which fluid controls to meter the nutrients in soil samples were miniaturized.
- Lightweight material weighing half as much as aluminum that can be used in leg braces and walkers for handicapped people.
- A fabric designed for astronaut space suits that has proved suitable for architectural applications. The fabric, a glass-fiber yarn coated with Teflon, has been used, for example, to roof an airport terminal near Mecca in Saudi Arabia, a department store in California, and the Silverdome stadium in Pontiac, Mich.
- Sportswear that removes heat by using a spinoff from the liquid cooling systems in astronaut space suits. The sportswear contains gel packets that absorb heat.
- Gortex, a lightweight heat-protective material for firefighters developed originally for astronaut space suits. The material is completely waterproof but allows moisture, vapor, and body heat to escape. It is also being used in ski clothing.
- A duck inventory being taken in North America by a nonprofit group that is using Landsat data.

—*T.S.P.*

posed ventures not as competition to the U.S. Space Shuttle, but as a complementary backup. Mr. Rector of General Dynamics said in testimony before a House committee:

"Ariane should not be allowed to take over the ELV [expendable launch vehicle] business unchallenged. Commercializing today's proven U.S. ELVs will provide a capability to accommodate the overflow in launch requirements in direct competition with Ariane."

Those operating the shuttle program agree that the private expendable rockets will complement rather than compete with the shuttle. General James A. Abrahamson, head of the shuttle program for NASA, said the expendable launch vehicles that survive will not compete with the shuttle but will offer special services in, for example, launching very small satellites or targeting satellites to special, nongeosynchronous orbits, and the larger, more complex orbital systems will be carried aloft by the shuttle. (This appears to be a change in NASA's stance, which originally leaned toward the phasing out of ELVs to remove competition for the shuttle.) At this writing, the Government had not released specifics on how it would make its launching sites and services available. A task force, led by the Department of State and NASA, has been set up to develop the implementation plan.

Waiting for the task force's conclusions are Federal Express, which has announced plans to commercialize Martin Marietta's rockets; General Dynamics, which will launch its own rockets; and Transpace Carriers Inc. of Washington, D.C., which plans to market and launch rockets made by McDonnell Douglas. And new players are springing up.

One company has already been successful without launching a rocket. Before the Government policy was announced, Klaus Heiss, former president of SpaceTran Inc. of Princeton, N.J., signed agreements with Martin Marietta and the other companies for commercial manufacture of the Titan rocket, with the agreement to become moot if the Government failed to act. After the Government's policy announcement in May, SpaceTran agreed to transfer its name, the agreements, and market studies and proposals to Federal Express. T. Allan McArtor, president of Fedex SpaceTran, the new Federal Express subsidiary, said that no money has changed hands and the companies are studying continued partnerships. Dr. Heiss indicated that "the agreed-upon payments are substantial."

Federal Express and its Fedex SpaceTran were welcomed by other companies entering the space-transportation business. The participation of such an established company places a stamp of approval on the fledgeling industry.

"I hope they paint the Federal Express logo on a rocket," Dr. Heiss said. "A rocket should have all the emblems—from STP, to diapers, to Coca Cola. Nothing looks better than an American racing car at Indianapolis with all those decals on it. When you see those decals on an American rocket launcher, you know that space is here to stay."

Some entrepreneurs did not wait for the Government to make the launching vehicles available but set out to develop their own. This became possible, noted Charles Chafer, vice president for government affairs of Space Services Inc., because "current breakthroughs in computer chips mean satellites do not have to be 18-foot Landsat buses that you send up on a Delta rocket or a shuttle, but rather they can resemble a breadbox—which means a lightweight satellite, a smaller launch vehicle, and much lower costs."

Space Services is trying to build that smaller launching vehicle. It is not intended to compete with the shuttle or Ariane or existing vehicles; it is being designed for lightweight, low-earth-orbit launches. The company has test-fired two rockets—the Percheron, which blew up on the launching pad, and the Conestoga [see Fig. 1, p. 49], which made a suborbital flight—and it plans its first commercial launching in mid-1985.

Another type of expendable launch vehicle is under development by Starstruck Inc. Roy McDonald, the company's director of public information, said that Space Services is using existing propulsion systems for its launcher, whereas Starstruck is developing a hybrid propulsion system that uses a solid fuel and a liquid oxidizer in the same motor. The company has decided not to buy an existing launching rocket, Mr. McDonald said, because, "while they are all good rockets, they are awfully expensive. We

are taking a purely private-sector approach, being ruthless on simplicity to increase reliability and cost-effectiveness."

The private sector is not ignoring the commercial possiblities of NASA's space shuttle. In fact, some entrepreneurs want to get their hands on one. Dr. Heiss, who founded SpaceTran, put together a group of investors who are interested in financing the construction and operation of a fifth shuttle. He has been pursuing this proposal for four years now, but the Government is undecided whether to allow private funding.

One problem independent companies have is obtaining permission from various Government agencies to launch a rocket, as the regulatory process is still poorly defined [see "Private launchings face regulatory unknown," p. 50]. However, the Government has established an interagency working group that will, the companies hope, straighten out the regulatory tangle before long. Uncertainty in regulation adds risk.

As more companies enter the launching business, the price of services seems likely to fall. Though the companies will compete initially for the communications industry's business, their presence seems destined to open up space to other commercial ventures. Space-transportation companies are admittedly counting on this growth in the market for part of their business, but they are not making their projections public.

Remote sensing: an uncertain market

Remote sensing, or using satellites to observe the land, water, or cloud cover, has been proved technically feasible and widely useful. In 1960 the United States launched the Tiros 1 weather satellite to begin routine observations of the earth's atmosphere. In 1972 the first earth-resources satellite, later called Landsat-1, was launched, followed by a series of more sophisticated Landsat models. No space company questions that data from remote sensing are valuable, but until now none has tried to put a real price on it, since the Government has been operating the weather- and land-observation systems as a public service.

But now a French company that plans to operate a commercial remote-sensing system is estimating that the return will at least equal operating costs of $400 million over 10 years, and two companies in the United States are also banking on a large market for remote sensing that they can profit from if the U.S. government stops giving away the information. The Government has said it will halt this practice. The Administration has decided that Landsat is to be transferred to the private sector or closed down by 1988. But the private sector may not want to take over Landsat. Though the technology may be ready for commercialization, most entrepreneurs think Landsat as a system is not. Designed as a research tool, it is very complex, with numerous capabilities—a Cadillac when users can only afford a Volkswagen.

The American Science and Technology Corp. of Bethesda, Md., is developing a low-cost remote-sensing satellite in a joint venture with Space Services Inc. The satellite is planned as Space Service's first commercial launching in 1985.

Terre-Mar Inc. of Mountain View, Calif., is also planning to commercialize remote sensing with its own system if Landsat is withdrawn. Don Walklet, president of the company, said that the next-generation system should be more cost-effective. Present costs for Landsat, he said, are too high to make a profit for a business. "It's quite unfair for the Government to think that we can afford Landsat without them giving it away," he said. "It is obsolete technology, complicated, and vulnerable to failure."

Before asking for bids from the private sector for Landsat, the Government asked for information informally in 1982. It got a response from Comsat. The communications consortium said it would buy the Landsat system if it was packaged with the weather-satellite system and the Government guaranteed the purchase of weather information. John L. McLucas, president of Comsat's World Systems Division, said, "I doubt I can predict that Landsat will ever go commercial in the normal sense. It has utility, but I don't know if it has enough utility to be commercial. Only weather information has such a huge demand, and then it's not commercialization in the usual sense, just a contract with the Government to supply the data."

Mr. Chafer of Space Services said, "Weather is irrelevant. It's just a way to get a Government subsidy, and we're not interested in that business."

Comsat is wary about going into the remote-sensing business without Government guarantees, because no one is sure how big the business might be. For the price of an earth station, which is somewhat expensive, plus annual royalties, or by purchasing data from the U.S. Eros Data Center, Landsat data are available to anyone in any country for use in map making, monitoring crops, detecting large schools of fish, making land-use assessments, and exploring nonrenewable resources.

While NASA developed a number of users of the Landsat data before turning the system over to the National Oceanographic and Atmospheric Administration (NOAA) to operate, the Government is not a marketing organization, and no real effort has been made to encourage people to ask for the data. Moreover, the existing users are not true customers, for they pay nowhere near the cost of producing the data.

Mr. Chafer, however, is enthusiastic about the commercial possibilities. "There is a huge market for data, but it's all potential," he said. "The Government has always said, 'Here's what we've got, folks. Come and buy it if you want it.' Even with that approach, there are an amazing number of ground stations and data purchases, but to be a business you have to market it."

Meanwhile the French company Spot-Image SA of Toulouse, a private company created to market data from remote-sensing satellites that have been developed, launched, and operated by the French national space agency, is moving ahead with its plans. In January 1985, whether or not the U.S. government continues to operate Landsat, the first SPOT satellite will be launched.

It was developed, said Gilbert Weill, president of the Spot-Image Corp. of Washington, D.C., the U.S. marketing arm, because many groups in Europe have been intrigued by the Landsat data but also have been frustrated. Europe has smaller fields for agriculture and smaller parcels of land in general than the United States, so Landsat's resolution has been inadequate for many applications in Europe [see photo]. The SPOT satellite is to have substantially greater resolution, as much as 10 by 10 meters per pixel compared with Landsat's 56-by-79-meter multispectral scanner resolution. (The Landsat thematic mapper, which has had operating difficulties, has a 30-by-30-meter resolution.)

To deal with the increased resolution in terms of data transmission and processing, the width of the scan is smaller for SPOT—60 kilometers versus Landsat's 185. SPOT, however, has a pointable mirror that allows several repeated scans of an area instead of a scan every few weeks—important in monitoring changes in the environment—and it also permits the construction of three-dimensional images with a technique that scans the same area twice from different angles. The 3-D approach is important for the assessment of mineral resources and for use in map making.

Manufacturing in space undergoing tests

When space-based manufacturing is considered in the United States, Government officials discuss it as an industry about to take off. "Why, take that McDonnell Douglas and Johnson & Johnson joint venture, for example," runs a typical comment.

"They'll be manufacturing drugs in space in a year or two. Oh, they'll have to get Federal Drug Administration approvals and all that, but pretty soon . . ."

McDonnell Douglas and Johnson & Johnson are using a process called electrophoresis to manufacture pharmaceuticals. Electrophoresis separates materials in a solution by subjecting them to an electric field. In a continuous-flow process, a stream of biological materials is injected into a solution flowing through a thin, rectangular chamber. The application of the electric field pulls the materials into separate streams, which flow out of the top of the chamber and are collected in separate tubes.

In gravity, the biological material will sink to the bottom of the chamber if it is heavier than the solution it is flowing through; therefore extremely low concentrations have to be used, limiting the amount of the sample that can be processed. Also, there are convection currents in a gravity environment, because of heating from the electric field, and these cause the particle streams to waver and exit through each other's outlets, thereby reducing purity. These and other gravity-caused problems are removed when the tests are conducted in space.

The space experiments conducted on shuttle flights proved that the amount of material separated can be increased nearly 500 times at purity levels four times higher. A production prototype of an electrophoresis system is being produced, to be flown on the shuttle in 1985. This is expected to manufacture enough material for a clinical trial. After that the company plans to seek FDA approval and to fly production electrophoresis units as shuttle payloads. Exactly what the company will be producing is a trade secret, but possibilities include an antihemophilic factor and also a possible cure for diabetes called beta cells.

"I think that we're beginning to see quite a lot of entrepreneurial activity in that field, as people see that there's money to be made," said NASA Administrator James Beggs. "If the entrepreneurial spirit in this country still lives, and McDonnell Douglas and Johnson & Johnson make a commercial success out of electrophoresis and make profits, then other people are going to sit up and take notice and say, 'Hey, there's money to be made up there,' and they'll get involved."

Microgravity Research Associates of Coral Gables, Fla., has signed a joint agreement with NASA to commercialize crystal growth in space, and its first project will be gallium arsenide crystals for semiconductors. The company's president, Richard Randolph, explained, "We believe we will make a significant enhancement of crystal structure that would be important to the upper-end users for more sophisticated apparatus." The first space experiment with crystals is to take place in 1986.

Project	Who	What	Status
Launch services			
	Arianespace SA Evry, France	Ariane expendable launch vehicle	Takes over Ariane operation from European Space Agency in 1984
	Federal Express's Fedex Space-Tran Corp., Memphis, Tenn.	Titan, Delta, and Atlas–Centaur expendable launch vehicles	Expressed interest, plans being evaluated
	Space Services Inc. Houston, Texas	Expendable launch vehicle being designed for low-earth-orbit, lightweight satellites	Successfully tested model, plans commercial launch in 1985
	Starstruck Inc. Redwood City, Calif.	Developing hybrid propulsion system for water-launched expendable launch vehicle	Tested sounding rocket, continuing development, expects commercial operation in 1985
	Otrag West Germany	Developing solid-propellant expendable launch vehicles	Stalled because of launch-site difficulties
	Transpace Carriers Inc. Washington, D.C.	Delta ELV manufactured by McDonnell Douglas	Negotiating agreement with McDonnell Douglas
	Space Projects Inc. Princeton, N.J.	Fifth space shuttle	Has contacted financiers, submitted proposal to NASA
	TranSpace Inc. Washington, D.C.	Proposing "Spacevan"	Still trying to obtain funding, planning a public offering by year-end
	Orbital Systems Corp. Vienna, Va.	A privately funded upper stage for use on the shuttle	Financing obtained, NASA agreement signed, system being developed
	USSR	Proton expendable launch vehicle	Bidding on contract to launch second generation of Inmarsats beginning in 1985
	Computer Sciences Corp. Falls Church, Va.	Atlas–Centaur	Has expressed interest to NASA
Remote-sensing satellites			
	Comsat Corp. Washington, D.C.	Landsat system	Proposes purchasing Landsats from Government if weather system were included and Government made purchase guarantees

Morris Khan

John Deere & Co. of Moline, Ill., has signed a technical exchange agreement with NASA to study alloy processing in a low-gravity space environment, first using nonorbiting facilities, such as aircraft, and eventually using a space vehicle. And last year the GTI Corp. of San Diego, Calif., signed a joint agreement with NASA to perform low-gravity metallurgical research in space, but the company recently canceled this project, which was to design a multiuser furnace that would operate in space for use by the metals industry. GTI said that the technical goal of designing the furnace had been achieved but that the company had concluded that "there is not at this time enough industrial interest to carry on a profitable business."

Other products are thought to have potential for improvement through manufacturing in space, including alloyed metals, which could be strengthened through uniform blending, and glass, which could be purified, since it would not come into contact with a container and could be spun into high-performance optical fibers for earth communications.

Much research needs to be done, however. Before the advent of the space shuttle and regular flights into space, the opportunities for experimentation in a microgravity environment were limited, and though there were many ideas about how to use space—even given the limitation that because of the transportation costs the resulting product must be worth at least $5000 a pound—facilities to test those ideas are just now being set up.

The McDonnell Douglas experiments were among the first conducted according to a joint agreement with NASA, under which NASA flies the companies' experiments free and the companies finance the experiment itself.

Not all shuttle experiments go smoothly or yield the expected results. An experiment sent up by the Japanese to study crystallization in space surprised its designers. A machine that manufactures snow from water vapor on earth failed to manufacture snow in space—the machine apparently worked properly, but the water did not condense. This result shows clearly that much basic research needs to be done.

A time of change for commercial communications

The U.S. government, in the Communications Satellite Act of 1962, authorized the formation of Comsat to act as a commercial communications wholesaler in the United States and to represent U.S. interests internationally, but the deregulatory environment for telecommunications in the United States has led to a competitive environment involving many companies, including Western Union Co., ITT Corp., and AT&T Corp.

Even more companies are jumping into the fray, however, with the advent of direct-broadcast–satellite (DBS) technology, which would allow consumers to put small satellite dishes in their yards and receive broadcasts from satellites directly. If this concept takes off, it could lead to an astronomically increased demand for satellite space.

Internationally the satellite communications business has been conducted under a global cooperative, a monopoly that shows signs of disintegrating as a number of nations launch satellites for regional use. The International Telecommunications Satellite Consortium (Intelsat), a coalition of nations, had held control since its formation in 1964. The Intelsat agreements specify that satellites launched for domestic purposes must be technically coordinated with Intelsat and that satellites launched for international purposes must not economically harm Intelsat.

But there is a feeling in the United States that it may be time for Intelsat's monopoly to end. According to Dr. Heiss, formerly of SpaceTran, "Domestically deregulation has proved tremendously successful. The question has to be answered whether deregulation worldwide might reduce costs to the principal users, provide a greater variety of services, and hence expand the market. Why not give it a chance, in a controlled fashion?"

At a conference on satellites held last December in Washington, Andrea Caruso, secretary general of Eutelsat—a regional satellite system in Europe whose very existence appears to violate the Intelsat agreements, since Intelsat defines any satellite that serves more than one country as "international"—pointed out that economies of scale are down to zero due to the cost of operating such a large organization. Eutelsat and other groups that wish to put up regional satellites prefer not to rely on Intelsat in heavily traveled paths of communication. "They," said Ray Williamson of the U.S. Office of Technology Assessment, "want to buy a second car to commute in instead of taking the bus."

Ready to offer private users an alternative to Intelsat is Orion Corp. of Washington, D.C., which has proposed a satellite that would offer "private facilities" across the Atlantic. The company's president, Thomas K. McKnight, argues that private facilities do not compete with common-carrier facilities, for he is proposing to sell, not lease, transponders that could not be preempted by priority users on his satellite, so companies would not be dependent on a service they cannot control.

But Intelsat views Orion's proposal as a threat and is attempting to block it by protesting to the FCC, which must assign an orbital slot to Orion. Orion meanwhile is moving along with its plans, obtaining letters of support (but not firm commitments) from 20 potential users, including governments, on both sides of the Atlantic and holding a reservation for launching on the space shuttle in December 1986.

"When television came out, newspapers considered it a threat because it would take advertising away, but really it increased the market," Mr. McKnight said. "That is what we are talking about doing."

Blue-sky plans for space

Looking beyond the currently feasible possibilities for commercial exploitation of space, space-manufacturing proponents talk about mining asteroids for nonrenewable resources. Space is also being considered as a possible dump for nuclear wastes. Visionaries see future developments in communications technology leading to personal communications systems, like Dick Tracy–style wristwatch radios, holographic teleconferences, and crime prevention through the distribution of distress buttons that would signal a public-safety transceiver with the exact position of its wearer. The latter is being proposed to the FCC by the Geostar Corp. of Princeton, N.J.

Other envisioned schemes include solar-power satellites, which would be parked in orbit to collect energy from the sun and transmit it to earth. But controversy over potential environmental hazards and high costs has stalled serious consideration of this idea.

And what about a space-tourism industry? NASA has established a task force that is considering when extra room might be available on the shuttle and how often civilians might be invited to travel into space. The agency has even been approached by a potential travel agent to develop a "space shuttle passenger tour." It would carry 100 to 200 people a year into orbit, beginning around 1990, for $1 million per person.

Though many ideas for commercializing space will never be developed, others will. "Some projects are going to bomb," said Gen. Abrahamson of NASA, "but some are going to develop quite effectively. We will never be able to have the U.S. reach its full potential as a space power and fully utilize space unless we can bring the resources of private enterprise to bear." ◆

2. SPACE TECHNOLOGY

The Apollo program has been cited by leaders of Japan's fifth-generation computer project as a perfect model to illustrate how a focused technological project can yield broad benefits far beyond its own mission accomplishments. In fact, it can be argued that the U.S. space program spurred technological advancements in every nation on the globe. Certain advances were necessary to get missions off the ground, so to speak, but those improvements also enabled more sophisticated missions later on. At the same time, these and other triumphs improved the way technology was applied in the commercial sector.

The case studies and chart that follow are not intended as all-inclusive of their respective disciplines, but highlight selected work and some of the fallout over the last 25 years. They are largely U.S.-based, but similar examples exist in the Soviet program. As other nations become more involved in space, their societies, too, will benefit from the fallout of technology from their space research and development. How this fallout has benefited the technical community in the United States is examined in the first article in this section.

Key to the Apollo mission, the most extensive project of the U.S. space program, was the development of a guidance and navigation computer, which enabled astronauts Aldrin, Armstrong, and Collins to land on the moon. As explained in the second article, Apollo set new standards of reliability and accelerated developments in integrated circuits.

However, there is more to space than Apollo. The Landsat series improved technology for land, ocean, and atmospheric remote sensing. Landsat has had an international effect, too, motivating the French to develop SPOT, which will become the highest-resolution imaging system ever flown for civilian purposes when it is launched in 1985.

In each of several other areas of space technology, one event stands out as most noteworthy. In telecommunications, it was the successful launch and operation of the Syncom satellites in 1963. That system demonstrated the technical feasibility of geosynchronous communications and became a prototype for the Intelsat system. In solar-power supplies, a crucial component for most space missions, Skylab is seen as the outstanding model, supporting the largest and most complex photovoltaic array ever flown. Indeed, photovoltaic work throughout the world has been led by developments in space missions. In fireproofing spacecraft, one area of materials science, radical changes were made after a fire killed three Apollo astronauts. Another area of aerospace technology, displays and controls, has advanced due to technology transfer between designers of airplane cockpits and spacecraft crew stations.

Finally, the benefits of the world's space programs extend beyond specific technologies to the management of large, complex, and integrated engineering efforts. Space programs have helped advance the status of systems engineering and the "systems outlook" more than any large technology-driven program yet undertaken.

These points are underscored in the following articles.

APOLLO: THE DRIVER AND THE DRIVEN

The sheer scale of the United States endeavor to land a man on the moon spurred a sweeping drive of technologies that have since fluorished independently. And the technological fallout from 25 years in space has affected the way we develop and manage technology and integrate systems of hardware, software, and people.

The National Aeronautics and Space Administration anticipated the depth of the impact early in its program to explore space, giving a grant to the American Academy of Arts and Sciences to study the massive technological enterprise of the space effort for its effects on technological diffusion, community structure, manpower, and society. The first volume of the study appeared in 1965. At the time Raymond Bauer of the Harvard Business School, who headed the active working group of the academy's Committee on Space, observed that "the major diffusion of technological innovation is likely to take place after its period of maximum development when surplus technologists are freed to work in other sectors."

That may be where we stand now, at NASA's quarter-century mark, though the diffusion point was reached sooner than expected. Space programs have come and gone so quickly that they have made many engineers and other technologists available earlier to other areas of application. Today many of the architects and engineers of the space program occupy pivotal positions in industry and academia. They have transferred not only technical ideas, but also managerial innovation, especially in the area of integrating large-scale systems. When NASA geared up for the all-out Apollo effort, perhaps the most ambitious total system project ever attempted by a civilian team, it attracted the best and the brightest to its in-house work force and to its contractors. The Apollo program was an astonishingly complex combination of expedient engineering and hundreds of inventions yet to be made. All were tied to a rigorous timetable involving an enormous variety of contractors and subcontractors who were drawn from almost every technical field and discipline.

Evan Herbert Contributing Editor

September 1983.

Because the Apollo program was tied to a clear national, albeit political, goal—beating the Soviets to the moon—NASA had several powerful factors in its favor. First, it was infused with almost limitless money, enabling it to enlarge its work force and to embark upon multiple approaches in solving problems. Up-front money also made it possible to support otherwise uneconomical development or manufacturing costs. For example, getting the high-reliability components for the Apollo guidance and navigation computer did not require major process innovation by the semiconductor industry; but the strict specifications for circuit reliability forced the setting up of multiple production lines and expensive quality-assurance programs.

Space-technology milestones

Spacecraft or satellite	Launch	Milestones
COMPUTERS		
Gemini 3	March 23, 1965	First on-board digital computer control. First glass delay-line registers and core main memory.
Gemini 8	March 16, 1966	First use of auxiliary storage in flight—a redundant three-track magnetic-tape unit read through voter circuits.
Apollo 4	Nov. 9, 1967	Saturn V launch-vehicle computer uses triple-redundancy and voter circuits to implement fault-tolerant approach to reliability.
Apollo 8	Dec. 21, 1968	On-board computer controls entire manned mission to circumnavigate moon.
STS-1[1]	April 12, 1981	Redundant five-computer, dual-tape memory system provides both aircraft and spacecraft control with fly-by-wire characteristics. First multiplexed data buses.
TELECOMMUNICATIONS		
Echo 1	Aug. 12, 1960	First passive communications satellite—a mylar balloon 30 meters in diameter.
Courier 1B	Oct. 4, 1960	First active-repeater orbited.Small signal loss but limited contact time. Ground stations had to track satellite.
Telstar 1	July 10, 1962	Demonstrated feasibility of wideband transoceanic communications via satellite.
Syncom 2	July 26, 1963	First communications satellite in synchronous orbit. No tracking needed and 24-hour access became available.
Early bird	April 6, 1965	First Intelsat satellite. First commercial communications made on June 8, 1965.
Communications Technology Satellite	Jan. 17, 1976	Pioneered use of Ku-band (12 to 18 GHz) in broadcast satellites. Extremely high antenna gain resulted in an effective isotropic-radiated power of 80 dBW, allowing use of earth receivers 40 cm in diameter. Prototype for direct-broadcast satellites. Joint project between Canada and the United States.
Marisat 1	Feb. 19, 1976	First maritime communications satellite. Signals could be received from and sent to moving ground stations on ships.
Direct broadcast Satellite	1984	First craft designed as a DBS will enable first entirely commercial communications satellite system. It will cover the entire United States.
Advance Communications Technology Satellite	1988	NASA satellite will receive and broadcast at 30 and 20 GHZ, respectively. Will have 18 fixed antennas, 6 multiple-spot beams, and on-board data processing and storage. Should increase capacity of present satellites by 100 times.
REMOTE SENSING		
Tiros 1	April 1, 1960	First satellite of NASA's earth-observation program took 22 952 surface photos.
Landsat 1	July 23, 1972	First earth-remote-sensing satellite. Spatial resolution was 80 meters.
SMS 8[2]	Feb. 8, 1975	First remote-sensing satellite in geosynchonous orbit and first one stabilized in three axes.
Seasat	June 26, 1978	First oceanographic remote-sensing satellite. Spaceborne synthetic-aperture radar proved useful for geological studies.
STS-2[1]	Nov. 12, 1981	Synthetic-aperture, or "imaging" radar, flown as a payload for the first time.
SPOT[3]	January 1985	Spaceborne sensors with the highest spatial resolution for nonmilitary uses is to be flown by France with Swedish and Belgian participation. Spatial resolution of 10 meters in black and white mode is expected.
SOLAR ARRAYS		
Vanguard 1	March 17, 1958	First photovoltaic-powered satellite.
Spaceflight 71-2	Oct. 3, 1972	First flexible-substrate photovoltaic array flown (by U.S. Air Force). Allowed large surface area to be rolled up into small stowage space. Rated at 1 kW.
Skylab	May 14, 1973	The largest photovoltaic power supply ever flown—21 kW. Power-to-mass ratio was 7 W/kg.
Hermes	Jan. 17, 1976	First photovoltaic cell array (1.3 kW) on a flexible substrate that folded like an accordian, decreasing weight as well as space. Flown by the European Space Agency.
Olympus platform	1988	First generic solar-powered platform. Multikilowatt flexible array (4 kW) will be flown by the European Space Agency and will carry communications satellites. Power-to-mass ratio will be 32 W/kg.

[1]Space Transportation System (space shuttle) [2]Synchronous Meteorological Satellite [3]Système Probatoire d'Observation de la Terre

A second factor aiding NASA was its firm, powerful control of the systems engineering process. Each of the development centers had a systems engineering division whose activities were integrated by a headquarters systems office. Moreover all NASA systems offices received additional technical support and advice from contract systems-engineering teams from companies like General Electric Co., Boeing Aircraft Co., and Bellcom (formed by AT&T to aid NASA). On questionable approaches it was possible to take multiple paths and to develop contingency plans for each risk.

A third factor in NASA's favor was the constant feedback to the Apollo systems-design engineers from astronauts and ground-support operators. This feedback had a major effect on software development and integration, which was recognized as so important to systems engineering that it was overseen from a single management viewpoint, that of the director of flight operations at the Johnson Space Center in Houston, Texas.

These three factors made it possible for major contractors to work together effectively, because interfaces were defined rigorously, with great depth of detail. The issuance of interface control documents compelled early resolution of any conflicts.

How well did it all work in practice? According to George M. Low, now president of Rensselaer Polytechnic Institute in Troy, N.Y., and director of the manned Spacecraft Center at Houston's Johnson Space Center during the Apollo program, "Perhaps the most important lesson of Apollo was deliberate design to minimize complex interfaces, thus making the systems-engineering task manageable."

The enterprise also holds lessons for conducting the business of technology. One aerospace industry veteran, James E. Ashton, vice president and general manager of the Tulsa division of the Rockwell International Corp., said, "The success of Apollo proved that even very large, terribly complicated goals can be achieved by breaking problems down into smaller problems and smaller goals. These then can be fenced in and treated as entities both from a business point of view, with contracts, and from a technical point of view, with interface-control drawings. Later the success of the shuttle orbiter proved the value of that concept to the design and apportionment of the system among many contractors."

Though the practice of engineering was driven to new heights by the space program, there were other effects that now profoundly influence many aspects of life. Robert Seamans, once NASA's deputy administrator and general manager and now the Massachusetts Institute of Technology's dean of engineering and head of its Energy Laboratory, credited James E. Webb, NASA's first administrator, for vision that went beyond his role in office. He foresaw the scientific aspects of being in space, the projected spinoffs into aeronautics, and the role that university research programs could play in ensuring success.

Mr. Webb so impressed President John F. Kennedy with this vision that he was able to get an unusual item in his budget: NASA support for several thousand doctoral candidates per year. He also got approval for a NASA grants program to put laboratories on campuses. This went beyond the need for specialized Government facilities, for Mr. Webb stated that he wanted research done "not only where the best minds would be involved, but also where the work would be tied closely to the educational process."

The NASA administrator asked the presidents of the 15 to 20 universities that received those grants to sign a letter saying they would make their best effort to set up a multidisciplinary activity on campus to look at all the ramifications of the space program. Not all the university programs germinated by NASA's grants program under Mr. Webb still have such clear-cut labels as MIT's Science, Technology, and Society Program, but multidisciplinary research flourishes.

Mr. Webb was also instrumental in the positioning of new Government laboratories. He insisted that they be established on or adjacent to campuses rather than in outlying industrial parks, so there would be "a fluxing of ideas with universities." Consequently a NASA Electronics Research Center was put right in the middle of Cambridge, Mass., within a stone's throw of four large universities, rather than in the high-technology–industry concentration along Route 128.

In a similar vein the unique concentration of scientists and engineers at space centers and test sites around the United States may have polarized the subsequent location of high-technology industry there. Inevitably such a concentration of talent upgraded education in surrounding communities, which in turn contributed new local talent to attract high-technology industries. ◆

COMPUTERS: LEARNING FROM DINOSAURS

Of all the electronic legacies attributed to space-age advances, computers share popular credit with communications satellites. However, history shows that fallout from space-flight efforts has led only indirectly to the $40 computers in discount stores today.

Pushing the state of the art was not what the National Aeronautics and Space Administration set out to do. Despite the ambitious, elegant language of the National Aeronautics and Space Act, NASA's early years were affected by the overtones of a race for the international political prestige to be garnered from manned space flight. When that objective was escalated to the unprecedented technological achievement of putting the first men on the moon and safely returning them to earth, the space agency sought proven—or at least provable—technology.

Despite ongoing advances in the science of computing, NASA elected to build and fly what might become computer dinosaurs. This convervatism turned out to be appropriate in terms of mission successes and the safety of the astronauts. But even the creation of dinosaurs affected the future of computing.

Valuable lessons were learned in designing computers to fit into small, tight spaces. Advances in software development and debugging emerged, including a new method for program interrupts that today is called memory-cycle stealing. And, most critical for the space effort, designers and vendors learned new approaches to component reliability.

As the Apollo moon shot effort moved into high gear in 1961, not all the technical problems had been solved. Eldon C. Hall of the Massachusetts Institute of Technology's Instrumentation Laboratory in Cambridge, who led the development of the Apollo guidance computer, reminisced that if his design team had known then what they learned later, they probably would have concluded they could not build the computer that was needed with the technology of the early 1960s.

As the manned space-flight program took shape, there was little question that the computer power then available could provide real-time guidance and control for the spacecraft. The tech-

Evan Herbert Contributing Editor

nology had been proved in most of the ground-based computers in existence in 1960. These were parallel general-purpose computers that had been designed in the late 1950s. The trouble was that few such machines, though they had the power for the contemplated moon missions, had been designed for the aerospace environment. Those that had been squeezed down to meet the size, weight, and power-supply parameters also embodied substantial compromises in computational performance.

The moon mission was extremely complex. It required enormous computing power that would be reliable and self-sufficient, for the spacecraft would be in a communications "shadow" during part of its translunar flight. Functioning as a general-purpose computer, the spacecraft's computer system would have to solve the guidance and navigation equations for the mission. As a control computer, it would handle such major functions as aligning the inertial measurement unit, processing radar data, managing the astronauts' displays and controls, and generating commands to control the engines.

On top of that, two computers were needed for the Apollo missions—one in a command module and the other in a lunar excursion module. This particular configuration of the Apollo spacecraft was the culmination of a technical controversy over whether the guidance problem for lunar orbit rendezvous could be solved at all.

Fortunately, rendezvous technology had been advanced considerably by military projects aimed at satellite interception. If it was possible to maneuver an unmanned inspection vehicle alongside an orbiting satellite, why not guide and dock together two manned spacecraft with essentially the same techniques? The guru of guidance and navigation, Charles Stark Draper of MIT's Instrumentation Laboratory, was so certain of the technological feasibility that he volunteered to go along on the first mission to run the computer.

The MIT laboratory had been working on basic guidance and navigation problems since the late 1950s under an Air Force study contract. From this work, on flight-path analysis for a spacecraft to photograph Mars and then return, emerged a unique design for a guidance and navigation computer. Though the Mars computer was never built, some of its features would be carried over into the Apollo guidance computer, as would the packaging techniques for a guidance computer developed by the MIT Instrumentation Laboratory for the Navy's Polaris submarine-launched ballistic missile.

By August 1961, MIT had received the NASA contract to design the Apollo guidance computer. The engineers of the Instrumentation Laboratory, which today is the Charles Stark Draper Laboratory Inc., were faced immediately with the constraints of top-down design. Within a week of President John F. Kennedy's proclamation that the United States would put a man on the moon, a reasonably well-defined Apollo spacecraft had been unveiled. The computer engineers were told they had a small hole in the equipment bay to fill with a functional system. It was to guide and control the entire flight to the moon and back, including rendezvous and linkup with the lunar excursion module. The area in the command module available for this task consisted of 1 cubic foot for the computer and some panel space for two display and keyboard devices for the astronauts [see photo].

To pack the system into that space would require high-density information storage. A suitable read-only fixed memory had been developed for the Mars computer. It was a core-rope memory, a transformer type that depends for its storage on weaving patterns into sensing wires at the time of manufacture. A stored bit is a 1 wherever a sense wire threads a core, and a bit is a 0 wherever a sense wire is not threaded through a core.

Though the content of a core-rope memory becomes unalterable, the medium is highly reliable, offering a density of 1500 bits per cubic inch, including all driving and sensing electronics, as well as interconnections and packaging hardware. At the time this was a 5-to-1 improvement over currently available coincident memory. There was room for six 6-kilobyte rope modules in the computer, offering 36 000 16-bit words of fixed storage, which would require advanced delivery of thoroughly debugged software so the information could be wired in.

The additional lead time imposed by hardwiring may have been responsible for the extraordinarily error-free mission performance of Apollo computers. It bought more time for checking and debugging after a memory had been manufactured for a particular mission.

Still, there was room for inadvertent error, as former Astronaut Jim Lovell recalls. He was the navigator on Apollo 8, the first flight to the moon to test the navigation capability of the system. On the return trip he accidentally punched up the wrong program, and the guidance system began to present information as if the spacecraft were still sitting on the launch pad at Cape Kennedy. It also lost all reference data to determine the attitude of Apollo 8 with relation to the celestial sphere. Mr. Lovell recovered by peering out the portholes for recognizable stars and manually updating the guidance system via the 2048-word coincident core-erasable memory to get the inertial attitude platform back into alignment.

Architecture and hardware contributions

Though the Mars computer design had provided some precedents, a significant contribution to aerospace computing archi-

tecture was a program-interrupt method of accommodating real-time inputs and outputs. Large-scale computers had begun to use it prior to the Mars project. The interrupt method was incorporated into the Apollo guidance computer for single access to memory to accomplish incrementing or shifting. This process, now known as memory-cycle stealing, has been widely used to link computers to peripheral devices.

One of the architects of the Apollo design recalls his reason for selecting core-transistor logic: it already was a proven technology, and the transistors would be turned on only when used, thus requiring less power. This translated into less weight and space.

Meanwhile the hardware technology available to aerospace computer designers was developing rapidly. Because the Air Force had been pushing the development of integrated circuits by the semiconductor industry since the late 1950s, it seemed to the project manager, Mr. Hall, that the burgeoning computer might be squeezed into state-of-the-art circuitry. However, he was concerned about reliability. An estimate of component failure rates and component counts showed that the resulting computer failure rate was too high to ensure a successful mission. Reliability could be increased by conventional techniques of redundancy, but the design would then exceed the requirements for power, size, and weight. The alternative was to seek computer reliability through more reliable components and manufacturing procedures.

The number of component types and range of values was constrained to a select few, bringing complaints from the circuit engineers that their designs would be constricted. An iron-clad flight-processing specification oversaw the quality of component lots. Defective lots were subject to wholesale rejection, with no partial givebacks. Vendors complained bitterly, but what they were forced to do in order to achieve reliability was underwritten by the ample budgets of the Apollo program. Later they accepted the reliability lessons learned from required internal visual inspection before crates were packaged or systems were sealed and all parts were burned in. As a result, the Apollo computer was a pioneer in the flight into space of nonredundant integrated circuits.

A delayed impact of software

Because the computer programs were entered into the core-rope memories by the actual manufacturing process, software had to be developed and debugged well in advance of each flight. By the time Apollo 11 lifted off the pad, the software team, led by Margaret Hamilton, had analyzed software management and development techniques and the software itself. The team found that 73 percent of the problems were interface-related— data and timing conflicts within the software. Moreover, 60 percent of the problems found in a given program release turned up in other releases already approved. Though they expected to solve the software reliability problem by eliminating errors, it turned out that a major improvement came from defining a system in such a way that interface ambiguities could no longer exist among the software modules.

The empirical study of the Apollo software enabled the categorizing of axioms and definitions for scanning whole classes of errors—program statements that were inconsistent, redundant, or logically incomplete. This effort evolved into a theory of higher-order software that was applied to system definition processes to get rid of interface errors. Ms. Hamilton set out to prove the theory, for she felt that it could be the basis for automating not only the verification process, but also the software-development process. She is now president of a company called Higher Order Software, with fully automatic software products that generate bug-free systems.

Impacts of other computer activities

Though the manned spacecraft program made the greatest use of the new capability of advanced computers, they were also used extensively for simulation, preflight checkout, launch control, in-flight monitoring, and data reduction from telemetry. James E. Tomayko of Wichita State University in Kansas said NASA enjoyed its greatest success in computer simulations. These allowed experiments with equipment and plans, as well as extensive crew training. Mr. Tomayko saw that the perfect flight record of the Saturn booster proved the efficiency of modeling that aided the development of the launch vehicle. He credits NASA's continued refinement and use of simulations to the fact that the space shuttle was man-rated on its very first flight.

The 4Pi series hardware and software used today in space shuttles was influenced by the special-purpose flight computer that IBM Corp. built for NASA's Gemini program in the 1960s. It made the first use of on-board auxiliary storage—a magnetic tape unit with identical programs on three tracks, read through voter circuits before the data entered the computer. It was another approach to reliability—through redundancy. Multiple redundancy and fault-tolerant equipment flies on today's shuttles in systems configured of five IBM 4P8/AP-101 computers and two mass-memory units. ◆

TELECOMMUNICATIONS: CLARKE'S LEGACY

While this year marks the twenty-fifth year of the National Aeronautics and Space Administration, another anniversary was marked this summer: the twentieth anniversary of the launching of Syncom II on July 26, 1963. Although there have been many significant events in the evolution of commercial satellite communications, none has had greater impact on this space technology than Syncom II, the world's first synchronous orbiting satellite. It demonstrated the technological feasibility of geostationary orbit communications, cemented the relationship between NASA and the commercial aerospace companies, and became the prototype satellite for the international Intelsat system, today the largest and most technically advanced communications satellite system in the world.

Three years before Syncom II went into orbit, NASA had inaugurated the era of satellite communications when it launched the balloon Echo I. Then Telstar I, built at Bell Laboratories and launched by NASA in 1962, demonstrated transoceanic communications via satellite [see "Space-technology milestones," p. 57]. But Echo was merely a passive reflector, and Telstar's orbit was too low, limiting its broadcasts to too little of the earth's surface to be economically useful. Also, both had to be tracked by ground stations, since their orbital period was not the same as that of the earth's rotation—a complex task even today.

The properties of geostationary orbit had been described as early as 1929 by the Austrian engineer Hermann Noordung, and a communications relay in this orbit had been predicted in 1945 by Arthur C. Clarke, a science-fiction writer. Simply put, a

New ACTS in communications

By the early 1970s, with the Comsat Corp. set up and the intelsat program a success, the United States satellite communications industry was flying high. So fast was the progress, in fact, that in 1972 Congress determined there was no longer a need for Federal investment in research and development. Funds authorized for this purpose by the National Aeronautics and Space Administration were dropped.

But by 1978 it had become apparent that this was a shortsighted decision. Satellites were crowding available North American orbital slots, and broadcasts of the same frequency in both the C (4 to 12 gigahertz) and Ku (12 to 18 GHz) bands were nearly overlapping. Causing even more alarm was the fact that both Japan and Europe were capturing larger shares of the commercial communications market.

In the 1982 budget Congress reappropriated funds to bring NASA back into the research and development picture. The Advanced Communications Technology Satellite (ACTS) program resulted. It should enable NASA to launch by 1988 a communications satellite with 100 times the capacity of present satellites in orbit. If successful, the demonstration model will establish a communications technology base in the U.S. sufficient to handle demand for three decades.

The satellite will make use of three new features. First, it will be capable of receiving signals at 30 GHz and transmitting them at 20 GHz (most satellites today receive and transmit at 6 and 4 GHz, or 14 and 12 GHz, respectively. The new capability will enable the satellite to handle a wider spectrum of signals. This will require improved radio-frequency components and antennas. Japan now has in orbit a 30/20-GHz satellite, the CS2A, and several European interests are working on similar systems.

Second, in addition to 18 fixed antennas, the satellite will be equipped with six multiple-spot beams, so it can transmit signals to highly localized areas on the ground. Different signals of the same frequency will be broadcast to different areas within the satellite's range, thus expanding the effective capacity of the satellite. On-board switching systems to control this operation are being developed. The television industry uses very high-frequency broadcasting in the same way. On Channel 2, for example, different programs are broadcast in New England, the Midwest, and California, because the broadcast coverage is localized.

Finally, the capability to process and store signals on board the new satellite will increase its capacity. This feature will be used when real-time communication is not necessary, such as when one computer sends a message to another. More importantly, the satellite will act as a switchboard in the sky for major telephone trunklines that are always overloaded, like that between Chicago and New York, directing traffic as it is received to the appropriate down link. The development of such a switchboard that can survive a launching and operate remotely in orbit is the challenge. —*M.A.F.*

satellite placed in geostationary orbit could make 24-hour telecommunications possible across a large portion of the earth's surface, and several coordinated satellites could provide worldwide broadcast coverage. What's more, ground stations would not have to track a satellite's movement; it remained in the same spot with respect to the earth's surface, effectively tethered there by a tower 22 300 miles high.

However, the prospect of achieving this goal in 1959 was bleak, recalled Harold A. Rosen, vice president of engineering at the Hughes Aircraft Co. in El Segundo, Calif., who began that year to develop a lightweight, geostationary communications satellite at Hughes. Launching vehicles at that time would not have been able to lift satellites then being considered for this purpose, and even if launchable, Dr. Rosen said, those designs called for hardware too complex to have a reasonable life expectancy.

"It then occurred to me," he remembered, "that the satellite's size and complexity could be greatly reduced if it were set spinning in its orbit." Spinning would simplify the satellite's control system and would permit a toroidal antenna beam to keep in continual contact with the earth. It would also simplify the orbit-control system. The simpler configuration resulted not only in better reliability, but it also lowered the satellite's weight. Additional weight was to be lost by use of a solid-state receiver.

Three advances made by three development team members at Hughes—Donald Williams, Thomas Hudspeth, and John Mendel—finally led to a simple, lightweight system, Dr. Rosen noted. The first advance was the method of attitude control; it relied on spin-phased impulses, which exploited the dynamics of the spinning satellite body, thereby reducing the number of attitude-control thrusters needed. The second was a series of receiver and antenna elements that were "years ahead of their time," Dr. Rosen said. And the third was a new rugged but lightweight traveling-wave-tube transmitter.

In 1960, the team began looking for a sponsor to launch its satellite. Its initial proposal was turned down by all U.S. and European government agencies and by every communications company approached. Critics doubted that the satellite would remain precisely in its orbit and that its antennas would stay pointed in the same direction. They also questioned the quality of voice communications via a geostationary satellite, because of the propagation time delay caused by the satellite's high orbit. Electromagnetic signals take approximately one quarter of a second to travel the 22 300 miles up to a geostationary satellite, be repeated, and travel back down to a ground station. For two-way communication, this means a half-second round-trip delay.

With that long a delay, any echo on the circuit muddled voice communications. But the team showed that echo suppressors could be used to reduce the interference. The suppressor, simply a voice-operated switch, worked well if only one person spoke at a time. Simultaneous conversation still presented problems, but this was not deemed a major complication by communications engineers. For television communications, a continuous broadcast, the delay would simply be adjusted for at the start of a broadcast.

Finally, in late 1961, Dr. Rosen's team persuaded NASA, in cooperation with the Department of Defense, to test its concept. The effort became known as the Syncom program (for synchronous communications).

But even as they wrestled with critics, the Rosen team realized that they needed a way to boost Syncom high enough to reach geosynchronous orbit, as well as a way to synchronize it once it was up there, so it would stay in place. The trick was to propel the satellite in three stages. Earlier low-orbit satellites, like Telstar, were simply inserted into desired orbits directly by the launching vehicles when the booster stage burned out. Syncom required an additional stage—an apogee kick motor, a small, solid-propellant rocket built into the satellite [see photo, p. 62].

The plan called for the launching vehicle to insert the satellite into an elliptical orbit with an apogee of 22 300 miles—the radius of a geosynchronous orbit. At that point the kick motor would fire to propel the satellite at 4000 mph in the direction of orbit, fast enough to lock it into a geostationary orbit.

"The idea sounds so simple," noted C. Lewis Cuccia, who was involved in satellite communications at Ford Aerospace Corp. at the time, "but someone had to be the first to do it."

Ironically it was the kick-motor phase that caused Syncom's

first failure. The first satellite was launched in February 1963, but it exploded when boosted into final orbit.

That July, however, Syncom II was successfully launched, demonstrating communications via a synchronous satellite (Dr. Rosen pointed out that it was not strictly a geostationary orbit, because the orbit was inclined relative to the equator).

It was then that the Comsat Corp., incorporated by the U.S. government the day Syncom I was launched, realized that if it hurried it could start business with a bang. The privately funded, quasi-governmental corporation had been set up to exploit satellite communications.

"Comsat said to itself, 'Hey, if we could get a television link to bring live coverage of the Olympics in Japan, we'd have a good kicker to start business,'" Dr. Cuccia remembered. Comsat approached him, he said, and told him he had three months to develop a receiver for this link. What resulted was the first telecommunications maser, a low-noise amplifier in which a signal is boosted by changes in the energy levels of atoms in a crystal. The amplifier was mounted on a relay station at Point Mugu in southern California, giving the station the added sensitivity it needed to relay signals from Japan. The live transmission of the opening ceremonies was carried by Syncom III, the first true geostationary satellite launched a few months earlier.

Noting the success of Syncom, Comsat contracted with Hughes to develop a similar satellite that was to become the first link in a global communications system operated by the International Telecommunications Satellite Consortium (now the International Telecommunications Satellite Organization, better known as Intelsat). The launching on April 6, 1965, of Earlybird, now referred to as Intelsat I, ushered in a new era of international satellite commercial communications in telephone, telegraph, and television. In one stroke, Intelsat I doubled the transmission capacity of all existing transatlantic cables. ◆

REMOTE SENSING: THE BEST VIEW IN TOWN

Remote-sensing satellites orbiting some 900 kilometers above the earth are still a source of wonderment to many space scientists and engineers. A sensor satellite "can see the whole world," said Dudley McConnell, an assistant associate administrator with the National Aeronautics and Space Administration. Both land masses and oceans can be viewed in the visible, infrared, and microwave portions of the spectrum. Weather-radar sensing, as exemplified by the Nimbus series, is thought of as being the highlight of the 1960s, the Landsat series that of the 1970s, and imaging radar that of the 1980s. Nonetheless, land-resources sensing, although only a small portion of all remote-sensing activities, is a powerful example of this technology.

Today, only 11 years after NASA's successful launching of the first earth-resources technology satellite, ERTS 1 (later renamed Landsat 1), data from these satellites are helping to forecast agricultural crop trends, explore for oil and minerals, monitor water resources, map vegetation and forests, plan land use, and produce geographic maps.

NASA has launched four earth-resources satellites so far--Landsats 1 through 4. The first two have finished their missions successfully, although they are still orbiting the earth. Landsat 3 is transmitting only about 60 percent of each earth image it picks up, and, as of last June, Landsat 4 was disabled because a cable carrying power from its solar array had failed, along with an X-band transmitter.

NASA officials were hoping, however, to receive data later this year through a backup transmitter in the Ku band. This transmitter is aimed at NASA's new tracking and data-relay satellite system, which was maneuvered into geostationary orbit last June after it had failed to achieve the proper orbit when launched from the U.S. Space Shuttle Columbia on April 4. NASA engineers are considering retrieving and repairing the ailing satellite during an upcoming space mission. Another alternative under consideration is the launch of a backup satellite for Landsat D next year.

According to Dr. McConnell, three technological developments have made remote sensing as we know it today possible:

1. The capability to mechanically stabilize satellites in three axes simultaneously.
2. The capability to scan a scene optically hundreds of kilometers away and to obtain enough meaningful detail about it.
3. The capability to derive useful information from large amounts of data.

Modest beginning in the mid-1960s

The debut of land remote sensing was modest enough. In the mid-1960s the Willow Run Laboratories of the University of Michigan, known today as the Environmental Research Institute of Michigan, introduced an airborne multispectral scanner. The development of techniques for extracting useful information from multispectral data and the study of practical uses of the data received a great boost when Landsat 1 was launched, according to Pitt G. Thome, a remote-sensing specialist who recently retired from NASA's Office of Space and Science Applications. Landsat 1, he noted, made large amounts of data available on a global and continuous basis.

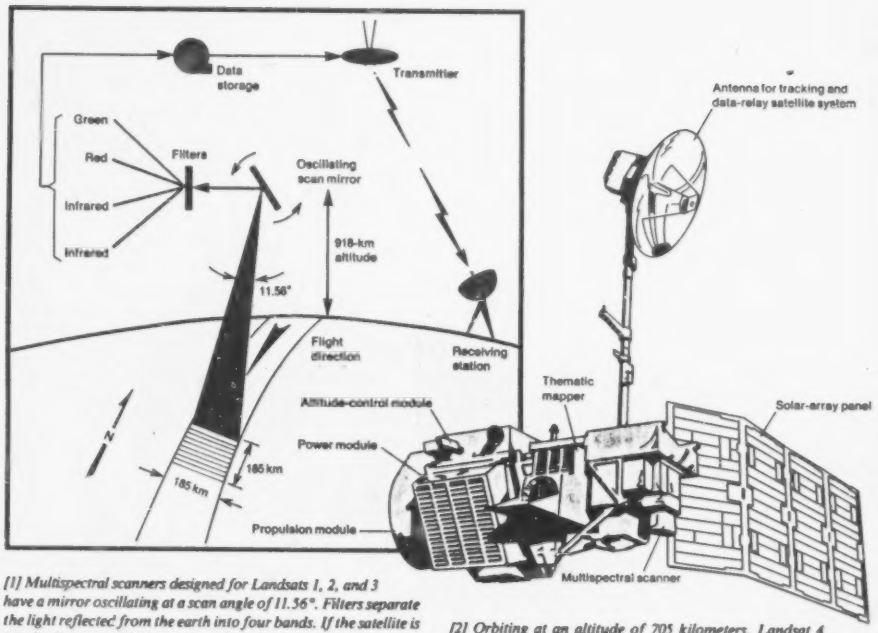
Gadi Kaplan Senior Associate Editor

composed of 6000 charge-coupled devices 13 micrometers apart are to be placed in each sensor's focal plane—one array assembly per spectral band—to pick up and respond to light reflected from the earth. Each line of the image is to be electronically scanned by a line of detectors within the array. Successive lines of the image are to be produced by the satellite's own movement in orbit.

NASA is currently supporting the development of similar technology under its multispectral linear-array program. The program includes the development of advanced multispectral detectors for visible light and shortwave infrared radiation, optics, on-board signal-processing technology, and sensor-design studies. Imaging spectrometers also are to be developed for testing during space shuttle flights beginning in 1987. More advanced sensors for shuttle missions lasting one month or so, as well as for space platforms for the 1990s, are also under study.

Data-processing bottleneck reported by NASA

There is at present a large operations bottleneck at Goddard Space Flight Center in Greenbelt, Md., where Landsat data are processed. Luis Gonzales, the Landsat 4 project manager there, noted that it takes a whole day to process just one thematic-mapper scene that includes seven pictures of a 185-by-185-km area, one picture for each of the seven spectral bands. Even with an expected increase in capability to 12 scenes per day, the processing rate would still be too slow; many images will have to be stored on tape until they can be processed. NASA is sponsoring an investigation into such areas as artificial intelligence, expert systems, and new textual-analysis techniques, hoping to find ways to minimize the delay. ◆



[1] Multispectral scanners designed for Landsats 1, 2, and 3 have a mirror oscillating at a scan angle of 11.56°. Filters separate the light reflected from the earth into four bands. If the satellite is too far from a receiving station, then the data are recorded and stored on board and are transmitted at a later date. (Figure adapted from a NASA drawing in Landsat Data Users Handbook.*)*

[2] Orbiting at an altitude of 705 kilometers, Landsat 4 carries a multispectral scanner and a thematic mapper. Each sensor scans a strip, or swath, of the earth 185 kilometers wide, with successive swaths overlapping to ensure complete coverage. Each swath is scanned every 16 days.

Today about a dozen nations have facilities that can receive and process data directly from Landsat 4. More than 100 nations use data from this satellite to help manage their resources. At the heart of this widespread use is a U.S. policy "to make Landsat data readily available on a nondiscriminatory basis throughout the world," Mr. Thome observed.

Landsats 1 and 2 are essentially identical: both include multispectral scanners [Fig. 1] and three high-resolution return-beam vidicon tubes, or television cameras, that provide black and white imagery. The spatial resolution of both types of sensors is 80 by 80 meters. Landsat 3 has a multispectral scanner and two identical broadband television cameras that produce black and white images at a spatial resolution of 40 by 40 meters.

The multispectral scanners on Landsats 1, 2, and 3 were designed to respond to light reflected from the earth in four spectral bands, covering green to infrared (0.5 to 1.1 micrometers). The multispectral scanner on Landsat 3 has an additional set of detectors for a thermal infrared band of 10.4 to 12.6 micrometers, although this band failed shortly after launching.

Meanwhile extensive analysis of data from Landsats 1 through 3 has shown that the data could be much more useful if the scanners could resolve scene elements one half to one third the size of 80-by-80-meter resolution elements, the smallest details these scanners can identify today. Furthermore, research with airborne scanners has shown that an additional band in the shortwave infrared region—1 to 2.5 micrometers—would be desirable to study vegetation and geological formations.

Additional research and development has led to a more powerful sensor known as the thematic mapper. Orbited on Landsat 4, along with multispectral scanners identical to those on the first two Landsat satellites [Fig. 2], the thematic mapper covers seven different bands: six of reflected sunlight in the 0.45-to-2.35-micrometer range and an infrared thermal band of 10.4 to 12.5 micrometers. Scene or picture elements (pixels) of 30 by 30 meters can be identified in the reflected light bands, whereas a 120-by-120-meter pixel is the smallest element detectable in the thermal band.

Spaceborne sensors with the highest spatial resolution yet for nonmilitary use are being prepared in Europe under a joint program conducted by France, Sweden, and Belgium. The sensors—two identical high-resolution instruments for visible light—are included in the Systeme Probatoire d'Observation de la Terre (SPOT) satellite to be launched in January 1985 as part of France's national space program. In orbit at an altitude of 832 kilometers, the sensors would have a ground resolution of 10 by 10 meters in a panchromatic band at 0.51 to 0.73 micrometers, and the resolution would be 20 by 20 meters if the sensors were used as multispectral devices in three color bands.

Because fine ground resolution is highly important, mechanical or "spot" scanning, such as in the multispectral scanners and thematic mapper, has been discarded by the European program in favor of an electronic method. Linear arrays

RELIABLE POWER: APPROACHING PERFECTION

The designers of Skylab's solar-cell arrays had good reason to worry after the spacecraft's launching on May 14, 1973. Part of the array assembly, they learned, had ripped off during the launching because of a mechanical problem. The power supply for the spacecraft was crippled. With just over 5 instead of 10.5 kilowatts available at any given time, Skylab's crew still completed the mission successfully. Once again photovoltaic arrays for spacecraft proved to be highly reliable.

Since the beginning of the space era no mission has ever failed due to solar-array failure, said Henry W. Brandhorst, who heads the space photovoltaic branch at the National Aeronautics and Space Administration's Lewis Research Center in Cleveland, Ohio.

What makes solar-cell arrays so reliable is high redundancy, stemming from the series and parallel connections of individual cells, according to Dr. Brandhorst. Because Skylab's photovoltaic system was the largest ever flown, the cell interconnections there were tricky. The system comprised two separate power supplies—one of a little over 10 kW for the Apollo telescope mount and the other a 10.5-kW system (this was damaged on launching in 1973) for use by the crew [Fig. 1]. The telescope's supply had more than 164 000 individual silicon solar cells, about three quarters of which were 2 by 2 centimeters and the rest 2 by 6 cm. The other supply had nearly 150 000 silicon cells, each 2 by 2 cm. The total area of each of the supplies was about 144 square meters.

Though typical spaceborne solar-cell arrays, such as those used in communications satellites, range 1 to 3 kW, Skylab's 20-kW system was a forerunner of things to come. In the next decade NASA proposes to put into orbit several sizable spacecraft, and perhaps a space station, which are expected to require large amounts of power for running experiments, handling data, controlling thermal conditions, and stabilizing the spacecraft.

NASA has also proposed that a special service platform, also identified as a power module, provide power and other services to other spacecraft. Services would be performed during docking in space. Variations on this idea are under study also at the European Space Agency's research and technology center in Noordwijk, the Netherlands, and at France's Centre National d'Etudes Spatiales in Toulouse. All three approaches call for anywhere from 20 to 30 kW to be available on the power module.

According to Klaus Bogus, head of the solar generators sections at the Noordwijk center, the solar arrays for such a future module would be light, highly modular, and easily deployable and retractable. They would operate at a voltage several times higher than that of today's solar arrays, he said.

Cheaper, thinner cells with higher efficiencies and larger areas are also being sought, according to Dr. Bogus. Work is under way in several countries on system, subassembly, component development, and such interconnection techniques as welding.

In the United States, NASA's George C. Marshall Space Flight Center in Huntsville, Ala., is preparing to test next year an

Gadi Kaplan Senior Associate Editor

September 1983.

array of thin silicon cells mounted on a two-layer blanket of Kapton, a flexible plastic material. The space agency sees this array as a radical departure from the solar array on Skylab. Supported by an aluminum honeycomb structure, the Skylab array offered 7 watts of power for each kilogram of array, said Dr. Brandhorst, whereas the goal for the new array is 66 W/kg. To minimize the costs of next year's test, only two of the array's 84 panels will actually have solar cells. When fully wired, such an array is expected to deliver 12.5 kW.

Though the primary purpose of the flight is to determine the deployment dynamics of this large, flexible structure, another objective is to obtain the operational characteristics of three types of solar cells. One type is 2-by-4-cm and another 5.9 cm on a side. Both are 300 micrometers thick and are capable of 13-percent efficiency. The third type will be 2 by 2 cm and only about one fifth as thick as the two other types. Its efficiency is projected to be 10.5 percent.

The European Space Agency is planning to launch in 1986 a satellite with a 4-kW solar-cell array on a flexible Kapton substrate, having successfully operated the experimental Hermes satellite with a similar, though smaller (1.3-kW), array from January 1976 to December 1979.

Gallium arsenide cells under development

Meanwhile NASA, the U.S. Air Force, and others have begun to develop spaceborne gallium arsenide solar cells as a major competitor to silicon. Research has already demonstrated that gallium arsenide cells are more efficient than silicon cells, are substantially lighter per given output power, can maintain acceptable efficiencies at much higher temperatures, and are expected to have twice the useful life of silicon cells because they are less susceptible to radiation damage.

To test gallium arsenide cell performance in space, the U.S. Air Force placed such a solar-cell array on a U.S. Navy satellite launched in February. Orbiting the earth at about 960 km, the array has 300 2-by-2-cm cells with efficiencies of 16 to 18 percent and total power of up to 25 W. The experiment is expected to last about two years.

NASA's Dr. Brandhorst indicated that the gallium arsenide processing technologies employed for photovoltaics are also useful in microelectronics high-speed circuitry. For example, researchers at the Lewis Research Center recently came up with a new technique for heavy doping of semiconductors in the production of a cascade cell structure. The technique is expected to lead to advanced microcircuits, Dr. Brandhorst said. ◆

THE SPACE-AGE MATERIALS CHALLENGE

When three astronauts for the Apollo 1 mission were killed in a flash fire aboard the spacecraft at Cape Kennedy, Fla., on Jan. 27, 1967, the threat of fire, a constant concern to one segment of space-materials scientists, was vividly realized. After the accident, the National Aeronautics and Space Administration moved to eliminate every possible fire hazard on spacecraft. At the same time, the Federal Aviation Administration began to examine comparable fire threats on airliners to see if they, too, could be avoided. NASA succeeded in its efforts, but few of the FAA's good intentions have been put into action.

Mark A. Fischetti Associate Editor

The fire broke out on the launching pad at 6:31 p.m. while the three astronauts—Virgil I. Grissom, Edward H. White, and Roger B. Chaffee—were taking part in a full-scale simulation of a scheduled Feb. 21 launching that was to take them to the moon. Emergency crews tried to reach the astronauts but were blocked by the dense smoke that rolled out of the cockpit.

Officials never were certain of the precise cause of the fire, but they concluded that an electrical short circuit had ignited materials in the pure oxygen atmosphere inside Apollo 1. NASA had known that the simplified atmosphere ran a risk of fire; in pure oxygen almost everything burns. The equipment needed for a two-gas system of oxygen and nitrogen, however, was deemed too heavy to fly.

"The assumption before that accident," recalled David H. Greenshields, assistant of NASA's structures division at the Johnson Space Center outside Houston, "was that although pure oxygen and flammable materials were on board, all the potential fire-ignition sources had been eliminated. The fire showed NASA could not count on that."

Spacecraft atmospheres since then have been gradually altered to resemble air and are today nominally 78 percent nitrogen and 21 percent oxygen. But NASA thinking has changed also. "Now," Mr. Greenshields said, "the assumption is that there is an ignition source."As a result, flammable electronics are contained in nonflammable containers, and construction materials are chosen so that "nothing will burn, even in pure oxygen."

With an ample selection of fireproof materials for spacecraft cabins, the problem is which to pick and test, according to R.L. Johnston, chief of the materials branch at the Johnson Space Center. After the Apollo fire, NASA turned to fire-retardant glass fibers for most of the seats and seat covers, flooring, wall panels, and packaging materials. With the advent of the reusable shuttle, however, a move to treated fabrics was made; glass material did not burn, but it wore through in only a few weeks of active use.

Poor wear and high cost, in fact, have prevented most commercial aircraft companies from using NASA's fire-retardant materials. One new material developed at the materials branch, however, may prove relatively rugged and inexpensive—a polyimide foam that can be used to construct airplane seats and floor and wall panels. It does not propagate a flame, and compared with currently used materials, it produces less dense smoke and fewer toxic fumes when it smolders. These are all important qualities, since the primary claimer of lives in airline fires is the inhalation of smoke from materials ignited by fuel fires. Both United Air Lines and Pan American World Airways are now testing panels made of the polyimide. So far, Mr. Johnston reported, the panels are wearing well and do not discolor.

Fire and smoke propagation have been well studied at NASA, and researchers feel astronauts are now well protected. But aside from the tests just mentioned and some limited work with the Boeing Aircraft Co. and the Federal Aviation Administration, the technology transfer to commercial airlines has not been great. The fire last June 2 aboard an Air Canada DC-9, in which 23 people were killed as the jetliner landed in Cincinnati, has revived longtime disputes over fire safety in airlines. Improved materials would not have prevented the fire, but they might have slowed its spread and more passengers might have gotten out alive. Though many air-safety officials agree that considerable progress has been made in fire-retardant materials research, they nevertheless contend that FAA regulations and industry standards lag far behind the state of the art. ◆

THE ART AND SCIENCE OF ERGONOMICS

Two questions that have dogged the designers of spacecraft crew stations concern how much information can be crammed onto a display before the display becomes confusing to astronauts, and how many controls they can effectively use. In the early days of space exploration, the designers of spacecraft got their answers from the builders of airliners. Today the airline engineers borrow from spacecraft designers.

In 1962, when John H. Glenn Jr. was lifted into orbit on the Friendship 7, how to best design displays and controls, and how to implement the instrumentation behind them, were decisions driven by technology already used in airplanes. But due to demand for more unique and specialized spacecraft in the 1960s and 1970s, epitomized by the space shuttle, crew-station technology has become the model for airplane cockpits.

Traveling at 17 500 miles per hour, astronaut Glenn saw four sunrises in five hours. He also saw a relatively simple instrument panel, which allowed complete control by the pilot but which reflected the minimal demands of the mission [Fig. 1]. In fact, the Gemini craft could have been remotely controlled from the ground. Astronaut Glenn, in his cramped quarters, relied strictly on toggle switches and needle gauges. Attitude information, for example [far left in photo], was displayed on three meters, one with a horizontal needle moving in the vertical plane and two with vertical needles moving in the horizontal plane. The circuitry behind the instrument panel depended on fuses, and there was no computing capability on board.

The same kind of toggle switches and needle gauges abounded in cockpits in airliners of the day, of which the Boeing 707 was typical [Fig. 2]. Desired features not included on Friendship 7 were color displays to help the crew differentiate between important readouts. But a three-needle system to show pitch, roll, and yaw was used, as on Friendship 7.

At first glance, the Boeing 767 [Fig. 3], introduced on commercial airlines this year, does not appear much different from its 20-year-old counterpart. But much has changed, behind the flight deck as well as on the panels. Electromagnetic equipment has been replaced by faster digital electronics, improving instrument performance. Denser circuitry has increased the capacity of on-board diagnostic equipment. Also, an inertial reference system using laser gyroscopes has been rigidly fixed to the jetliner, replacing the gimballed gyros set spinning on earlier planes. Color cathode-ray-tube displays, first flown aboard Skylab, and digital readouts have replaced most of the needle gauges.

The three-needle attitude system, for example, has been replaced in the 767 by a CRT display centered in front of each flight-control column. It shows attitude information and the orientation of a graphics symbol of the actual plane being flown on an artificial horizon. This idea is repeated in the radar system (the second CRT in front of the column, below the attitude indicator). It provides an integrated multicolored map of the plane's position relative to waypoints and instrument-landing-system beams. A colored radar display can be superimposed on the map to show weather conditions. The airplane's position with respect to the ground, and any deviation from a preplanned route can also be displayed, lessening interpretation demands on the crew. Overall, there are fewer controls and meters than in the 707, even though the 767 is a larger and more complex craft. This has simplified the crew's tasks enough to permit optimal operation by only two people, rather than three in the 707.

By the same token, the space shuttle is also more complex than Apollo crafts were, but only a commander and pilot are needed to carry out all flight functions, compared with Apollo's three-man team. Many of the instrumentation advances in the 767 were based on those already in the shuttle, which was built by Rockwell International [Fig. 4]. Moreover, the shuttle, preceding the 767 by two years, goes the airliner one better, performing like a spacecraft in flight and an aircraft during landing. Color CRTs show the shuttle's attitude and its position after reentry from space with respect to landing beacons and other aircraft. Computer data and text are also displayed. The pushbutton flight deck, the digital electronics and microprocessors behind it, and the greater visibility and room to move about are all quite a change from the cramped, toggle-switch-controlled, fuse-dependent Friendship 7. ◆

SUPERPROJECT MANAGEMENT

Not since the Manhattan Project atomic bomb effort of World War II had there been such a massive mobilization of technical talent in the United States as that started in the late 1950s to conquer space. Backstage it was replete with the rivalry of competitive technological approaches to objectives that initially were defined in only the broadest of terms.

Suddenly systems thinking was forced to gel by the imposition of a political timetable. Another Soviet space triumph on April 12, 1961—a man in space only three and a half years after Sputnik had become the first object into orbit—sparked concern that the USSR planned an even greater space spectacular for its 50th anniversary. U.S. officials speculated that the Russians would be shooting for the moon and so they set out to get there first. The U.S. goal: men on the moon by 1967 or earlier.

In astonishingly short order, often after only months, earth-based and space systems had to be born all at once, rather than be allowed to evolve. To meet the timetables, systems were carved into an enormous number of technical tasks and parceled out as projects. The output of these projects, both hardware and software, would have to mesh with exquisite precision with a timetable conceived even before technological feasibilities had been confirmed.

As the space race became increasingly political, it was put on a fast track and lubricated with money, a factor that enabled multiple technical approaches to be tried in parallel. The space agency opened in October 1958 as the National Advisory Committee for Aeronautics, an organization with a long record of technical excellence, though not much autonomy and political influence. The committee totaled 7900 people, most of them in its research laboratories and test centers, with 170 as a Washington headquarters staff.

Strengthening the aerospace infrastructure

By the time the Soviet Vostok 1 returned to earth in 1960, NASA had 17 000 people on its staff and was supporting industrial contracts involving 60 000 more people. By mid-1960, private industry was being groomed for a major role in the manned space-flight program. Most of the work would go to contractors.

But NASA was organized to exercise consistently strong control of every aspect of systems engineering. George M. Low, who headed the Manned Spacecraft Center, emphasized the tremendous strength centered in the relatively small project offices run by NASA's in-house work force. "The key to success," he said, "was a design that recognized the overall complexity of Apollo and separated the system into as many individual pieces as possible, with minimum interfaces."

The project offices at each of the Apollo Development Centers—the Johnson Space Center, the Marshall Space Flight Center, and the Kennedy Space Center—had systems engineering divisions that were integrated by a similar systems office in NASA headquarters. Contract systems-engineering teams from industry gave technical support to those divisions and separate checks and balances for the headquarters office.

When the Apollo program was put into high gear, a broad top-down design of the spacecraft had already been accomplished. Systems integration of the many functional subsystems was still a major challenge. The Apollo systems engineering approach deliberately anticipated the magnitude and nature of this challenge. For example, the decision to separate the spacecraft into command and service modules, and ultimately a lunar module, was to minimize complex interfaces. In fact, there were only about 100 wires between the spacecraft and the launch vehicle; the systems engineering between them was confined to the docking interface. Few determinations had been made of what actually would go into the boxes in a total system scheme that included launching, ground support through a global network of tracking and communications stations, space-vehicle guidance and navigation to the moon, lunar landing and exploration, and safe return to earth. Three contractors were assigned to help. Bellcomm, part of Bell Laboratories, assisted with the overall systems planning. GE was charged with overall testing and checkout. Later, after the disastrous Apollo fire, the Boeing Aircraft Co. was brought in to keep track of the intermediate stages—ties among the mechanical, hydraulic, electrical, electronic, and other systems.

Most of the prime contractors were aircraft and missile companies, accustomed to analog instrumentation and controls. The venture into space would require on-board equipment compatible with the experience of aviators turned astronauts. Moreover the equipment would have to be designed for in-flight repair if needed, which meant that failure detection and diagnosis was essential. Thorough and rapid checkout of tens of thousands of connections and signals would also be required on the launch pad. When it appeared that digital computing was the only way to run the spacecraft and the checkout, most of the subsystem designs were forced toward digital techniques.

Feedback from astronauts encouraged

As program elements were committed to design and development, NASA instituted a uniquely personal system of feedback from the very people who would use the equipment—the astronauts themselves. This practice made for useful, though oddly disturbing, effects on equipment design. The first group of seven astronauts consisted mostly of experimental test pilots. They expected to fly the spacecraft, rather than be flown in it.

The next nine astronauts were essentially flying engineers and contributed considerably to the technical directions being taken, although some, on their first visits to the Instrumentation Laboratory at the Massachusetts Institute of Technology in Cambridge, where a digital Apollo guidance and navigation computer was being developed, threatened that once they got up there, they would "turn that thing off." Ultimately a design was devised that permitted each procedure the computer was about to execute to be displayed for review by the navigator or pilot, giving him the option of telling the computer to proceed.

With the multiplicity of technical approaches encouraged by NASA, and with contractors and subcontractors layered many tiers deep, NASA field centers were kept aware of technical and program information via technical liaison groups, tracking information, instrumentation, and guidance and control. A huge computer data base accessed by remote terminals became a model for technical information storage and retrieval.

Nevertheless, it was tight control, centered in a few specific, responsible managers, that accomplished the system integration. For example, Mr. Low made Chris Kraft, his director of flight operations for the Johnson Space Center, responsible for the entire software development, ensuring that from the systems point of view the spaceborne and ground-based software could work together. What's more, one of Mr. Kraft's operations chiefs, Bill

September 1983.

Tindall, was assigned to the Spacecraft Program Office and developed logic diagrams for every operation that might take place during an Apollo mission. These logic diagrams led to the proper use of each system, fed back into the system design, and were the key to the operations manuals for each flight. "Without them I doubt whether we would have landed on the moon with Apollo 11 when the on-board systems appeared to be overloaded and a ground-based controller told the astronauts to ignore the overload signals," Mr. Low said.

The strong influence of a computer

A single subsystem, the Apollo guidance and navigation computer, influenced the decisions that ultimately were made about the moon. Because the computer was at the heart of both the main spacecraft and lunar module that would be used, it had inside-out influences on most of the other subsystems with which it interfaced. In a system like Apollo, designed to facilitate and support manned space flight, the interfaces are not only between hardware and hardware and hardware and software, but also between hardware-software and human beings.

Different specialists had different ideas about how to go about beating the Soviets to the moon. "Some of these were really hairy," NASA's Deputy Administrator Robert C. Seamans recalled, "like shooting equipment to the moon until everything was up there to be assembled into a spacecraft by the lunar crew for its return to earth." The concept of a lunar orbit by the main spacecraft, to be followed by a rendezvous with a lunar module, also seemed farfetched when it was first advanced by John C. Houbolt of the Langley Research Center in Hampton, Va. But the success of this concept hinged on precise guidance and navigation of both the command and lunar craft.

NASA's Management Council assessed the probability of success of a mission plan based on lunar orbit and rendezvous and urged its adoption. The decision to proceed was announced in July 1962. By October the Grumman Corp. had won the contest to build the lunar excursion module (LEM), which would become part of project Apollo.

There was no precedent for the vehicle Grumman was to build; it was not an aeronautical but purely an astronautical subsystem. And within that system Grumman wanted its own guidance and navigation computer. NASA insisted that both the command module and the LEM must have identical computers.

Later, on Apollo 13, as former astronaut Jim Lovell remembers, this decision to engender standardization was a saving grace. When the explosion of an overpressurized cryogenic oxygen tank damaged an adjacent fuel cell, almost everything in the command module, including the computer, was shut down to conserve the little remaining electric power. The LEM was used as a lifeboat until the crippled Apollo could be maneuvered onto a free return path to earth. To restart the command module computer, the LEM computer transferred needed information on position, velocities, and length of time in space.

The tricky business of interfacing

The MIT Instrumentation Laboratory team developing the Apollo guidance and navigation computer had its own interface design philosophy. Fortunately it was one firmly supported by NASA, for the computer electrical interface design was frozen before that of many other subsystems.

The MIT interface objectives that were to prevail stated: standardize as much as possible, use simple circuit configurations, develop wide but uniform specification limits, and use low pulse-repetition rates and duty cycles. These approaches made interface control documents more difficult to negotiate, but anticipated systems-integration problems hard to correct later.

Because the computer processed pulses by cycle stealing (processing many inputs at the same time), it risked being saturated. So one objective of the interface negotiations was to keep the data rates low. A limit of 3.2 kilohertz for the input/output counters was set. The number of interface circuit types was held to four, thus increasing reliability by extensive use of standard circuits and yielding more experience with circuit limitations and operational peculiarities.

The concept of wide tolerances in the interface specifications allowed for compatibility with many circuits and reduced the criticality of circuit design. But Eldon Hall, who led the computer system project at MIT and is still with what is now the Charles Stark Draper Laboratory, cautions that the wide variation allowed in a specification sometimes frustrated the achievement of what appeared to be a desirable objective. The designers wanted to ensure that the interfaces would not be sensitive to pulse shape and would be required only to distinguish the presence or absence of a pulse. However, a few subsystems that interfaced with the computer required critical timing that used the rise and fall times of the pulses.

Managing interproject communication

Committees and design-review processes spurred communication among the engineers and organizations working on the Apollo systems. Typically the guidance and navigation committee met regularly to review interface-control documents, electromagnetic interference specs, the test plans of the Raytheon Co., which built the computer, and the test plans of AC Electronics, the prime contractor for the guidance and navigation subsystem.

As for design review processes, there were several within the computer subsystem project. A very formal design review by NASA looked downward through the overall Apollo system. This was followed by an equally formal MIT review, of drawings and specs that were to bear the NASA imprimatur upon release, performed jointly by the Instrumentation Laboratory and the support contractors. The composition of this team kept changing, sometimes consisting mostly of design engineers and at other times largely of production engineers. This fluctuation underscored the close cooperation required, because design, breadboarding, and prototype production went on in parallel.

When design changes were needed, the process proved cumbersome to manage because of the contractual arrangements that had been instituted to permit the chopping up of tasks into projects running in parallel. Sometimes the process became an open loop; contractual details were processed through a different channel from the documentation for design changes. One area that needed elaborate procedures for control and documentation was software development. Because there were different Apollo flight mission programs to be stored in core-rope fixed memories, a "rope mother" was given complete responsibility for each computer program. Margaret Hamilton, who led the software development, said that the Apollo software systems still remain among the most elaborate ever produced. They affected almost every technical activity of the entire Apollo project. A hierarchy of review processes required changes to be signed off by a software designer, the rope mother, NASA, and every prime contractor and subcontractor who might be affected. The bureaucracy became so extensive that it almost required too much trouble to institute a software change.

Bureaucratic form and practices were inevitable in a project as gargantuan as Apollo. One of the management lessons seen in retrospect may be knowing where in each development phase one chooses the method and rigidity of control. ◆

3. THE POLITICS OF SPACE

(c) 1983 IEEE. Reprinted with permission,
from IEEE SPECTRUM, Vol. 20, No. 9, pp. 26-98,
September 1983.

WHO OWNS WHAT? EARTH LAW FOR SPACE

Periodically throughout history mankind has had the opportunity to develop legal theories to meet the demands of advanced technologies. But advanced technology has only rarely produced whole new arenas for human interaction where no laws govern the interaction. Space is one such arena.

In the quarter century since the Soviet Union and the United States catapulted man into space, major areas of international law have become fair game for legal theorists. New laws controlling activities in space are desperately needed, but the hurdles in the way of creating them are enormous.

S. Neil Hosenball
National Aeronautics and Space Administration

Among the major hurdles are these:

- Exceptions taken to space treaties by countries that decline to be signatories to the treaties, or who wish to get around provisions in treaties they have signed. Equatorial nations, for example, are claiming control of any satellites placed in geostationary orbit over their lands even though an international treaty signed by over 90 nations permits no claims of sovereignty in space.
- Demands for restrictive treaties not likely to be viewed as acceptable to some major democratic nations. Many nations, including some Western European countries, are deeply concerned that direct-broadcast satellites will bring the undesirable transmissions of other nations into the homes of their citizens via inexpensive dish antennas.
- The concern of many nations over the inadequacies of current space treaties to control certain types of weapons from being tested, deployed, and used in space.
- Lack of international law to apply to private industry and to human interactions in space. Countries have by treaty, for example, surrendered any claim to territory on planets and celestial bodies, but they have retained legal control over their citizens. What happens if a citizen of one country assaults a citizen of another country in space, say? Which country's laws apply?

All of these areas represent virgin soil for legal doctrine. Two areas with a similar heritage are the law of the sea, stemming from navigational advances that permitted exploration of the world, and the law of airspace, necessitated by the ability to fly over territorial boundaries. At first competing interests in the sea and land were often resolved by conflict. In time disputes between competing interests were solved largely by the application of existing principles of sovereignty, the creation of customary international law, and the negotiation of international agreements.

The legal problems associated with outer space, however, are not subject to traditional sovereignty solutions. What is generally meant by the term "sovereignty" is that a state is self-governing; that it has authority to enter into diplomatic relations with other states and to make agreements with them in the form of treaties or conventions; and that it has freedom to control or dispose of its own territory and its own military forces. However, the acceptance of customary international law or any treaty by a state means that a state has surrendered some of its absolute supremacy or independence.

Current space law

With the three major characteristics that define sovereignty as guidelines, to what extent have states surrendered or retained sovereignty in space or over space activities? In December 1958, just one year after the Soviet launching of Sputnik I and less than two months after the establishment of the U.S. National Aeronautics and Space Administration, the United Nations established an Ad Hoc Committee on the Peaceful Uses of Outer Space. The purpose of this committee was to examine ways in which the UN could promote international cooperation in the exploration and use of space and identify any potential legal problems in this area.

After the committee had issued its report in 1959, the UN established a permanent Committee on the Peaceful Uses of Outer Space, which has negotiated and reported out to the General Assembly five treaties for signature by member states. The principal document, the "Treaty on Principles Governing Activities of States in the Exploration and Use of Outer Space Including the Moon and Other Celestial Bodies," promulgated in 1967, is considered the charter governing space activities. Over 90 of the 157 member states of the UN have signed it.

Perhaps the principal virtue of this treaty is its provision in Article II that outer space, including the moon and other celestial bodies, is not subject to national appropriation by claim of sovereignty, by means of use or occupation or by any other means." Throughout history nations have acquired territory through conquest or exploration. But because of the 1967 treaty, the United States did not claim sovereignty over the moon or any part of it after the lunar landing.

Despite the language of the 1967 treaty and the U.S. compliance with it, however, all the equatorial countries stated in the so-called Bogota Declaration of December 1976 "that the geostationary synchronous orbit is a physical fact linked to the reality of our planet because its existence depends exclusively on its relation to gravitational phenomena generated by the earth, and that is why it must not be considered as part of the outer space.

"Therefore, the segments of geostationary synchronous orbit are part of the territory over which equatorial states exercise their national sovereignty," the Bogota Declaration concluded.

It has been said that sovereignty is a trumpet blast employed to emphasize a state's honor, independence, and grandeur, and sovereignty is also invoked when a state does not wish to accept something under international law—particularly when the exception may yield significant economic, political, or national security advantage. The use of the geostationary orbit some 22 300 miles above the equator has obvious economic, political, and national security value. And when there are economic, political, and nationalistic issues, but no clearly established and enforceable law or treaty or clear sovereignty to resolve the issues, major international conflict becomes all too possible.

Technology is soon to be at the heart of a second crucial debate: what to do about the direct-broadcast-television satellites. The Soviet Union, the Eastern Bloc countries, and a significant number of developing countries assert that they have a sovereign right to control all information entering or leaving their country, whether it be print, radio, or television. They take this position notwithstanding that various declarations on human rights, including the Helsinki Accords, recognize the principle of free flow of information and the right of peoples to receive or impart information across national borders. They are particularly concerned about direct-broadcast-television satellites because of the economic, political, and cultural impact that television may have on their countries. At the 1982 General Assembly meeting a UN resolution establishing principles to be applied to direct-broadcast-television satellites, including one requiring consultation and agreement between the broadcasting and receiving states, was passed by a vote of 107 in favor of and 13 against, with 13 abstentions.

National security and the sanctuary concept

Potentially the most contentious area of all in space affairs is the military use of space. No arena better illustrates the looming clash of sovereignty notions than the desire of much of the world to apply international law before space becomes yet another realm for armed conflict.

So far, the superpowers have largely used their space technologies in the form of surveillance satellites to increase their security and that of the world. But many nations and individuals have been alarmed by the Soviet programs in antisatellite weapons and laser and particle-beam research. And recent U.S. attempts to keep up with the Soviet Union concern many citizens.

It is not that there is an absence of international law that can be applied to the military uses of space. There are many limitations on the sovereign rights of states, as well as provisions that reserve these rights to the states. Under the disarmament provisions in Article IV of the 1967 treaty, states that are party to the treaty undertake not to place in orbit any objects carrying nuclear weapons or other weapons of mass destruction, or to install such weapons on celestial bodies, or to station such weapons in outer space in any other manner. Article IV also forbids the establishment of military bases, installations, and fortifications and the testing of any type of weapon in the conduct of military maneuvers on celestial bodies. Article III of the 1979 Moon Treaty prohibits any threat or use of force on the moon or other celestial bodies. But none of these provisions prevent the superpowers from testing weapons in space, and as more nations become capable of placing satellites in space, the kind of bilateral negotiations process discussed by Ambassador Robert Buchheim on page 38 of this issue may not suffice to maintain space as a weaponless sanctuary.

Four more treaties followed the 1967 space treaty. For example, the Convention on International Liability for Damage (caused by space objects) makes states that are party to the treaty liable for damages resulting from space activities when such damage occurs on the earth or to aircraft in flight. Where injury or damage occurs between two artificial satellites in space, states are liable based on a fault theory. The Liability Convention does not, however, extend to damages caused by space activities on the moon or other celestial bodies, and the Moon Treaty specifically reserves the question of under what rule of law liability for damages occurring on the moon or another celestial body will be determined. Also, the Liability Convention does not provide for a binding award. Any award by the Claims Commission is only a recommendation, and each state reserves the right to decide whether to pay such an award. The Agreement on the Rescue of Astronauts, the Return of Astronauts, and the Return of Objects Launched into Outer Space commits a state to waive its territorial sovereignty if an astronaut or spacecraft makes an unplanned landing in its territory. Under this treaty, the state is obligated to return the astronaut or spacecraft to the state of origin.

Authority over people and enterprise in space

Though states under the Outer Space Treaty may have given up their rights to claim territorial sovereignty in space, on the moon, or on celestial bodies, they have under Article VIII of the 1967 Outer Space Treaty retained their legal authority over their citizens when they travel into space or reside on the moon or other celestial bodies. Article VIII of the 1967 Treaty states that a nation launching objects into space shall "retain jurisdiction and control over such objects and over any personnel thereof." Further, according to Article VI of the treaty, the activities of nongovernmental entities in outer space—private industry, for example—"shall require authorization and continuing supervision by the appropriate state party to the treaty." From these provisions it appears that states have retained their rights to exercise their sovereign authority over their citizens whether in space or on the moon or on celestial bodies, just as they have the right to extend their sovereign authority over their citizens whether resident in their own territory or the territory of a foreign state here on Earth.

This bifurcation of territorial sovereignty from the exercise of sovereignty over citizens may cause many problems when outer space—the moon, other celestial bodies, or space platforms—become populated by human beings living, working, and carrying on commercial activities. On Earth two persons of different nationality, both of whom are in the territory of the United States, are subject to U.S. law because of U.S. sovereignty over its territory. If one committed a crime against the other, U.S. law

would apply notwithstanding that one may be a citizen of some other nation.

But if these same two were on the moon, where no nation has sovereignty, whose law would apply? Suppose they wanted to marry, or a child were to be born, or they wanted a divorce, or there were a question of custody of the children—the whole range of ordinary legal matters affecting the personal legal status of persons—what law would apply?

Extending international commercial law into space is also problematic. In space, whose law would govern the organizaton of business entities, the financing of such entities, and the commercial law applicable to business transactions between parties of different nationality?

Who should make space law?

In seeking to determine what law will govern activities in space, a fundamental question, perhaps more political than legal, is what kind of legal system will develop? Will space law be comprehensibly international, with a supreme international authority having enforcement jurisdiction, or will several states or other kinds of jurisdiction be carved out and permitted to develop laws of more or less local nature? Or will private conduct be largely unregulated, with legal principles and enforcement authority established to deal with particular situations as they arise?

Will the residents of a celestial body invoke Article III of the 1967 Outer Space Treaty, which says that activities in outer space including the moon and other celestial bodies shall be conducted in accordance with international law, including the Charter of the United Nations? The United Nations Charter contains in Article I (2) a provision that the friendly relations between peoples, which it is a function of the United Nations to promote, shall be based on respect for the principle of a people's right of self-determination. The self-determination principle may mean that every people has a right to determine whether it shall be an independent state or be joined to another state. The term is also used in the sense of the people's right to decide on the constitution under which they desire to live. The lack of territorial sovereignty combined with the principle of self-governing would seem to permit a space colony to develop its own laws or regulations independent of Earth. This appears to be true whether the colony were multinational in nature or composed largely of the citizens of a single nation on Earth. It would appear, for example, that a colony of U.S. citizens on the moon would be in a position to demand statehood as the 51st state of the Union by threatening otherwise to declare itself an independent nation.

These are just a few significant examples of the potential clash between sovereignty and international law as applied in space. As can be seen, there are theoretical problems that today may be largely academic. But as the exploration of outer space and the celestial bodies takes on a more permanent and extensive form, the structuring of a governing legal system may become a more practical problem.

The Ad Hoc Committee on the Peaceful Uses of Outer Space considered the establishment of an international authority to enforce the law applicable to outer-space activities but found that no autonomous intergovernmental agency should be created at this time nor should an existing agency be asked to undertake overall responsibility for space matters. In the past, legal rules, particularly with respect to novel areas of human activity, have not developed until there was a certain level of practice or agreement among the persons, entities, or states involved. The broadly phrased provisions of the Outer Space Treaty reflect the consensus on applicable legal rules that can be achieved at the present time. Except for the establishment of general principles, specific laws will have to follow the application of science and technology. Premature establishment of legal regulations as the result of inadequate information may serve to hinder rather than advance development of outer space. As ventures are launched into orbit and beyond, a body of law will follow that will attempt to preserve the development of outer space for the benefit of those living there and for all mankind. ◆

4. THE FUTURE OF SPACE

(c) 1983 IEEE. Reprinted with permission,
from IEEE SPECTRUM, Vol. 20, No. 9, pp. 26-98,
September 1983.

Where will technology and politics lead us in space? The pages that follow include several articles by men intimately involved in setting the course of the U.S. space program. George A. Keyworth II, the science advisor to President Reagan, edges closer than he previously has to backing a permanently manned space station. "If U.S. citizens are asked to make an installment payment [on] a space station," he writes, "they should be allowed to share the grand vision of the future of space." One such vision, he adds, might include "a manned lunar station, or even manned exploration of Mars."

In another article, James Beggs, administrator of the National Aeronautics and Space Administration, foresees "a new era of truly international cooperative ventures in space" by the year 2008, when NASA will celebrate its 50th anniversary. Using the exploration and scientific settlement of Antarctica as a model, Mr. Beggs summons visions of multinational expeditions "charting pathways to the planets and the stars."

Concluding this section is an article by Senator John H. Glenn Jr., the former astronaut, who presents his personal agenda for U.S. space activities for the next quarter century. Calling for the establishment of a space infrastructure—including a permanently manned space station and a number of unmanned space platforms for scientific and applications purposes—Sen. Glenn details the next great leaps forward in space-based telecommunications, earth observations, and materials processing. He announces his personal support for renewed solar-system exploration and challenges the Government to support private enterprise and help reinvigorate U.S. space research and development. Finally, on the weaponization of space, he says, "It would be in the interests of both the United States and the Soviet Union to enter negotiations to reverse the trend toward and to eliminate any weaponization of space."

LOOKING AHEAD IN SPACE

In one of the classic examples of national vision and leadership in the postwar era, President John F. Kennedy anticipated and articulated the readiness of the United States to take a giant step in manned space exploration. The goal he offered was deceptively simple—a man on the moon by the end of the decade. And the nation responded—with ingenuity, enthusiasm, and dedication.

George A. Keyworth II
Executive Office of the President

We know now that Kennedy's call in 1961 for the Apollo program was a brilliant stroke. With astute political timing, he capitalized on three of the traditional strengths of the U.S. citizenry—its pioneering spirit, its technological expertise, and its competitiveness—to promote a renewed sense of national unity. In truth, the nation had little real reason to doubt its leadership then, especially in technology. But the launch of Sputnik in 1957 by a supposedly backward, unfriendly nation shocked and challenged the United States. That was the starting gun for its entry into the "space race" with the Soviet Union, a race that in retrospect turned out to be no contest at all. With hardly a look backwards, the United States, through the Mercury-Gemini-Apollo programs, led the world into the modern space age.

It was a classic example of a program that drew upon a society's resources. In particular, the U.S. space program was a product of the country's broad and advanced industrial and technological base. It drew on expertise in areas such as propulsion, materials, electronics, computers, space science, tracking, and navigation. Most important, it took advantage of the ability of U.S. engineers to integrate those technologies into reliable and efficient new systems. The United States entered the 1960s with space technologies in mind; it ended the decade with those and better technologies in hand.

Whether the age of space is measured from the half century since Goddard's pioneering experiments, or from the World War II rocket developments in Germany, or from the launch of Sputnik, it is clear that the United States has achieved a remarkable level of proficiency in space technology in a short time. It has successfully challenged a monumental frontier, and in the process it has reaped immense psychic, political, and technological rewards.

When I was a child, man's occupation or use of space was true fantasy. Today my own children take those capabilities for granted and wonder what other marvels the future will bring. Undeniably, the 1980s offer a broader set of options than the United States could have envisioned realistically just a generation ago. Today space technology and space operations are maturing fields.

Near-term space science and exploration

What can we foresee in the next decade and beyond for the U.S. space program? Let us look first at some of the more obvious elements, those things I would characterize as evolutionary developments.

First on my list are the purely scientific and exploratory missions. Although they no longer dominate our space activities as they once did, I confess that they still excite me the most. I'm especially intrigued by the Space Telescope, which may be the most important advance in observational astronomy since

Galileo's first crude telescope.

Ground-based observers have struggled for years to pierce the atmosphere with larger mirrors, faster emulsions, and electronic detectors. Their quest has taken them all over the earth in search of darker nights, clearer skies, and stiller air. In a few years, with a new perch above the atmosphere afforded by the Space Telescope, astronomers will get a truly spectacular view into a new dimension of the universe. Soon after, the launch of the Gamma Ray Observatory will permit a new spectral window on astrophysical phenomena, just as the advent of X-ray astronomy did in the 1970s. These two new scientific tools—the Space Telescope and the Gamma Ray Observatory—represent significant leaps in the sophistication of space-based instrumentation. I hesitate to predict what new horizons they'll reveal, but I am waiting with keen anticipation.

Man's understanding of the solar system has been growing over a span of two decades—from the early Ranger and Surveyor mooncraft, to the more recent spectacular observations of Saturn by Voyager II, to the exciting prospects for the Galileo missions to Jupiter. What began as an attempt to explore the nearer planets has evolved into a comprehensive program of scientific measurements and observations.

But in recent years these individual missions have become more complex and immensely expensive; as a consequence, they have become less frequent. In the past few years it became apparent that this stretching out of missions was threatening the ongoing vitality of the field of planetary science, especially its ability to attract new people. So in the past year the United States has taken steps to encourage simplified—and less costly—planetary probes so that it could afford more of them.

The planetary science community, making a transition from older exploratory programs to newer experimental ones, has devised a plan of affordable, effective missions that does not conflict with other research priorities. The Venus Radar Mapper, the first probe in a new program of planetary research, bodes well for renewed excitement in this field.

Observing and serving the earth

In another area, one of the earliest discoveries in the space age was the complexity of the magnetic and solar phenomena that surround the earth. Now the opportunity arises to use new space-observation techniques to see how those solar-terrestrial phenomena influence weather and climate as well as the growing global communications systems. Likewise, those same vantage points above the atmosphere—whether on orbiting satellites or on interplanetary probes—will continue to provide new insight into the evolution of our solar system and give us firmer knowledge of how the earth came to be.

In a more immediately practical sense, U.S. scientists will continue to take advantage of orbiting instruments to examine the earth, its features, and its resources. Broad-spectrum remote sensing of weather, ocean dynamics, biomass patterns, and mineral resources has reached sophisticated levels.

Communications is perhaps the most highly developed application of space hardware; the tremendous investments by commercial ventures, both in the United States and elsewhere, are evidence of how ingrained communications satellites have become in modern life. These applications to communications

will be increasingly influenced by such favorable factors as very high operational reliability, long service life, increasing satellite size, and increasing data-transfer rates.

The space shuttle: a wealth of possibilities

But by far the most important demonstration of the maturing space capability of the United States is the U.S. Space Shuttle, now a veteran of seven missions. Today the shuttle can almost routinely place large payloads in orbit; it also has the potential to revisit low-orbit payloads for maintenance and retrieval. It is important that the United States fully exploit these features in order to reap a substantial return on an immense investment.

Further, the shuttle is much more than a launch vehicle. It is a flexible manned space platform for research and development, with the potential of developing into an enormously capable space system. In fact, the shuttle–Spacelab combination is both larger and more capable than the Soviet Union's Salyut–Soyuz combination. To optimize its use of that shuttle–Spacelab capability, the United States can extend the length of time these vehicles can remain in orbit. Currently that period is limited to about seven days, but it could be extended to 20 or 30 days without great cost or risk.

The shuttle is also capable of placing large modules in a low-gravity environment. For years there has been talk about the potential for manufacturing ultrapure materials and undistorted crystal structures in space. We are about to see how real that potential is, with the joint McDonnell Douglas and Johnson & Johnson drug-manufacturing process leading the way. Obviously the shuttle's ability to revisit automated factories will be critical to the near-term potential of these emerging technologies.

Finally, access to space is increasingly important for national security. Satellites conduct regular surveillance of ground activity over much of the earth and enhance the military's ability to communicate and navigate. It is unfortunate that some of the more impressive examples of U.S. space leadership cannot be more widely appreciated because national security forbids their disclosure. The important point is that these technologies have reduced the possibility that the United States would be caught by surprise by either new deployment of weapons or mobilization of troops by an adversary. Particularly in a nuclear age, no one can tolerate surprises.

Competing realistically in space

So far, I've described future prospects in space development. I would characterize these projected developments as evolutionary activities. But the United States should consider revolutionary changes too. To do that, it must look at the realities of today and compare them with the realities that President Kennedy faced a generation ago.

In 1957 Sputnik was not a real challenge to the nation's security or economic well-being. But it did threaten the self-image and international prestige of the United States. Economically and militarily the country was secure, so it had no hesitation in responding to Sputnik with an ambitious space program to reclaim its national pride, to recapture its political prestige, and to reassert its technological supremacy.

That was a quarter century ago. Today the United States faces real—not symbolic—competition from other countries. It is confronted by an increasingly aggressive Soviet Union, which has continued a massive military buildup that transcends any reasonable requirements for its defense. At the same time an industrially revitalized Europe and Japan challenge the nation's economic leadership.

The response to this round of challenges is more difficult, requiring a long-term strengthening of the nation's base in science and technology. The United States needs new knowledge and new skills to make its products and services better, to expand markets through invention and innovations, and to increase the effectiveness of its military forces. Unlike the 1960s, when the country could more or less take for granted the adequacy of this base to serve its national needs, today it must make heavy and wise investments in its scientific and technical talent and facilities.

So in this new era of competition for resources, the nation is challenged to find the most effective and appropriate role for its space program. The question is not: Can the United States afford a large space program in light of these other priorities? Rather the questions are: How can the United States fashion a space program that addresses today's national aspirations and needs? How can it use its investments in space to bolster its science and technology base and to reignite the spirit of adventure that captured its people in the past?

Let me suggest two complementary approaches toward meeting this great challenge. Like an evolving company, the U.S. space program has options for both horizontal and vertical expansion. It can continue to build on experience and it can also move into newer, more exploratory, and inevitably less well-defined directions.

Let me offer one example of vertical expansion. I said earlier that the shuttle is far more than just a launch vehicle and that an effort should be made to take better advantage of its sophistication. At one time the shuttle was expected to meet almost all civilian launching needs. But I think that is a misutilization of its capabilities. Instead, smaller, simpler, and more mundane launching requirements should be met with existing expendable launch vehicle (ELV) technology.

President Reagan has encouraged development of commercial launching services that capitalize on past investment in ELVs, such as Atlas–Centaur, Delta, and Titan. Not only would such a development make the shuttle available for more elaborate missions, but it would also bring a desirable new element of competition into routine launching services. This competition should give foreign ventures in commercialized space launches a run for their money.

Several firms are emerging that combine entrepreneurial marketing skills with aerospace experience. It will be interesting to see how the forces of competition, with aggressive marketing and cost reductions in launch services, stimulate increased use of space in the future.

This balance between commercial ELVs and the shuttle could offer even more flexibility and security to U.S. space efforts. So I would characterize the evolution of commercial launch services as a kind of vertical expansion. Conversely, horizontal expansion would require revolutionary new ventures in space exploration. These would be the kinds of initiatives that open new frontiers, develop new technologies, or recapture the sense of national unity that Apollo did.

How far should man go in space?

Not surprisingly, now that the shuttle is becoming operational, there is more and more discussion about large new ventures in space—in particular, manned space efforts. Let me dismiss one factor that is frequently raised—the fact that the Soviets seem to have a more advanced man-in-space program. In truth, the Soviet effort reflects the relatively less sophisticated state of their technology, in terms of automation and equipment reliability. The United States, on the other hand, has shown how much can be achieved—and how much more cheaply—by using high tech-

nology to carry out many of the functions that would otherwise require hands-on operation.

The real question is not whether the United States should emulate the Soviet Union, but whether it can inject a new sense of vision into U.S. space exploration. The most often discussed and most immediate possibility is a manned space station, serviced by the shuttle and composed of modules supporting a broad spectrum of space activities. This was the original objective of shuttle development a decade ago, and the needed technology appears to be within reach.

However, any of the kinds of space stations being discussed would be expensive—costing many billions of dollars. I question the return on that kind of investment because it is not clear yet what would be done with the station once it were completed. Some people have jumped to the conclusion that I have a bias against a space station because I insist on a valid mission before making any commitment. That is not true. But I think it is time for us to take a broader look at where we expect the U.S. manned space program to go over the next quarter century.

Most advocates of a space station readily acknowledge that it is only an intermediate step in the more ambitious long-range goal of exploring the nearby solar system. If U.S. citizens are asked to make an installment payment in the form of a space station, they should be allowed to share the grand vision of the future of space—whether it is an orbital transfer vehicle to provide manned access to high geostationary orbits, a manned lunar station, or even manned exploration of Mars. Surely the Apollo experience has shown that the United States can be strongly supportive of ambitious new programs if the citizens share the vision and if they are convinced that important national needs are being served.

Exploring the future

The National Aeronautics and Space Administration is examining these various options, especially the space station, and its studies should provide the basis for important choices. But ultimately the major decisions about the nation's course in space must be based on a strong national commitment. Those decisions will necessarily involve considerations of cost, benefit to the nation, and impact on the overall space program. And most important, they will depend on how a major new program would influence the United States' ability to meet looming challenges to its economic future and its national security.

Even while the United States considers those larger space projects, there are several immediate steps it can take. It can, and must, fully exploit the shuttle-Spacelab concept and continue to involve the private sector in space and space-related activities. These steps are necessary if the nation expects to develop a sufficient industrial, economic, and scientific and technical base to continue to be the leader in space exploration. More important, these steps will also help maximize space capabilities over time. The United States is in an enviable position to take advantage of its leadership in electronics and space technology and to continue to build a rock-solid foundation for the next stages of the space program.

There is also one additional use of space that may come about in the near future and that could change fundamentally the way we perceive the world. I refer to President Reagan's proposal on March 23 that the United States devise a strategy that emphasizes defense over offense—in particular, defense against nuclear attack. Such an advanced defense system would almost certainly involve space technology.

One prediction seems safe enough. Space science, exploration, even defense, will increasingly be international in scope. This is consistent with our approach to other kinds of "big" science, which is growing too expensive for individual countries to continue to pursue on essentially parallel tracks. Just as many nations share the results of space science and explorations, it is time for them to share more of the financial responsibility, too. Otherwise the United States will be increasingly constrained in mounting the kinds of imaginative scientific missions that take advantage of developed space technologies.

Space is a place to be careful, but not to be timid. The present dialogue, even the controversy, is appropriate for a nation confronting difficult decisions in a difficult time. ◆

NASA'S DUAL CHALLENGE: SERVING YET STRIVING

With 25 years of leadership in space behind it, the National Aeronautics and Space Administration is at a crossroads as it faces the next quarter century. Organizations such as NASA are means to accomplish the ends of those who create and sustain them. Fundamentally, it is impossible to discern NASA's future evolution without knowing what path in space the United States will choose from among the many options available; the outlook for NASA depends on the goals selected by the Government for the next quarter century's space efforts.

Twice before, in 1961 and in 1982, U.S. Presidents proposed, and Congress agreed to, multibillion-dollar investments of public funds in a space project—first the Apollo program and then the U.S. Space Shuttle. Now NASA is hoping to develop a permanent, manned station in space.

This aspiration is a logical next step for an agency that, while accomplishing many unmanned science- and applications-program goals, has for two decades been nurtured by its manned projects. At the same time, NASA is attempting to deal with issues unlike any it has faced in the past. It is being asked to help commercialize broad sectors of space activity, to maintain a U.S. leadership position in the international space competition with Europe and Japan, as well as with the Soviet Union; and to work in close partnership with other civilian agencies, the Department of Defense, and the private sector.

Such relationships, to be effective, will require a very different NASA than now exists; thus, the challenge that faces NASA today is whether it can both develop a space station that is broadly useful to the country and make the adaptations required to encourage private-sector initiatives in space.

NASA's evolution: off to a fast start

What was unique about NASA in its first decade was the rapid mobilization into a single organization of high-quality technical and managerial personnel and expensive facilities, plus the coupling of that organization with a network of industry and universi-

ty activities. The aim was to create for the United States a preeminent capability to operate in space. Although NASA opened for business in 1958, it was not until the May 1961 call of President John F. Kennedy for a space program "which promises dramatic results" that the space agency became transformed into a potent and aggressive technical organization carrying out a high-profile, politically driven mission.

At the peak of the Apollo program, NASA had a budget of $5.25 billion (equivalent to almost $19 billion in 1983 dollars), employed 36 000 people, and was supported by an industry and university team composed of 377 000 people, as well as facilities representing an investment of over $4 billion. The organization was dominated by development engineers who had an expansive view of the future in space. That orientation was appropriate for Apollo, but it has caused problems for the agency ever since.

Where to go from Apollo

After the moon, what? NASA's answer to that question was first made public at almost the same time as the initial lunar landing. At the Apollo 11 launching, Vice President Spiro T. Agnew, who was heading a top-level review of post-Apollo space policy for President Richard M. Nixon, told the assembled news reporters that "we should articulate a simple, ambitious, optimistic goal of a manned flight to Mars."

NASA found this prospect quite appealing. Within a few days the agency had added a manned Mars mission during the 1980s to the plans it had been developing for several years. Those plans already called for a 12-person space station to be placed in earth orbit by 1975; a 50-to-100-person space base by 1980; a permanent manned base on the lunar surface in the same year; a "grand tour" of all the outer planets of the solar system by unmanned spacecraft; and, almost incidentally, an earth-to-low-orbit reusable launch vehicle to resupply the space station and to rotate its crews. That vehicle was called the space shuttle.

Implementing this plan, NASA contended, would "expand this nation's capacity for space flight as far as foreseeable development in technology will permit." While NASA's leaders may never have expected approval of an early Mars mission, they did hope to develop a space station and a space shuttle during the 1970s, and the Mars objective gave a focus and a justification that were otherwise missing.

This ambitious set of proposals was a reflection of what NASA had become during the Apollo years: an organism that was more responsive to its own internal technological momentum than to externally developed objectives. However, the nation's political leaders rejected NASA's vision of a space program that was driven primarily by technological feasibility. That rejection has been frequently reaffirmed in the years since then. After Apollo, the United States decided that it wanted a space program tailored to scientific, economic, and national security payoffs. President Nixon and Congress concluded that the motivations that undergirded NASA's first decade—national prestige, national pride, and symbolic competition with the Soviet Union—were no longer of top priority.

However, President Nixon did not want to end the manned space-flight program; he believed the astronauts were valuable for national morale. Also, there were beliefs among those concerned with space policy—accepted more on faith than evidence—that the space frontier was just opening, that there were a variety of future missions with high payoffs for society, and that human involvement in space operations was likely to be important.

Given these factors, the space shuttle program emerged as a logical next assignment for NASA. Although there would be no

space station to which the vehicle would "shuttle," a reusable launcher could be justified in terms of increasing the capability for, and lowering the cost of, all forms of space activity; making access to orbit routine; keeping human crews involved; and preserving the option to develop a space station at a later time. Moreover, the shuttle was intended to be a national space project, serving civilian and military users alike, and not just a NASA launch vehicle.

The space shuttle reveals NASA's predilections

For most of the past decade, NASA has acted as if it had forgotten the reasons why the shuttle had been approved and has tried to run the project as if it were another Apollo program. NASA had projected a busy future for the civilian and military space program of the 1980s. It had argued that the space shuttle would lower the cost and increase the flexibility of operating in space and could be developed on a budget low enough to allow many other NASA science and applications programs to thrive. Considerations of user compatibility, technical simplicity, minimizing operational costs, meeting development schedules, and staying within an approved budget were submerged as NASA's engineers became fully engaged with the shuttle and found out just how complex a development task it was. The vehicle that has been created is much closer to a high-performance, but temperamental, Jaguar than to the "space taxi" that was promised.

The technical challenges of the enterprise dominated NASA's existence during the 1970s, and many of the agency's other projects and proposals were deferred in order to procure the funds required to solve those challenges. Only as schedules slipped and budgets increased did NASA begin to get the project under firm control and shape it to the uses for which it had originally been intended. This is a task that continues today.

NASA is in 1983 an institution with an almost schizoid character. Its leaders talk of commercialization, user-friendly systems, smaller spacecraft for solar-system exploration, and the need for a space station to support the needs of industry, the scientific community, and the military. Much of NASA's heart, however, still seems to be linked to the excitement of manned missions and astronaut heroes, to the opportunity of developing large space systems, and to visions of exploring the planets with both men and machines.

NASA in 1983 is also still a highly capable technical organization, although it has shrunk in size and perhaps competence since its heyday. The current work force is just over 21 000, down almost 40 percent from 15 years ago, and this year's NASA budget has less than 40 percent of the purchasing power of its 1966 allocation. The NASA field centers remain top-flight scientific and engineering organizations. Many of the NASA staff members who were attracted as young engineers and managers by the Apollo buildup 20 years ago are still there in mid-career, still eager to tackle challenging technical problems. If NASA does not offer those challenges in the next several years, then its best people may be tempted to switch to other work and bright new graduates will not be attracted to the agency; indeed, such a "brain drain" may already have begun. The NASA facility and equipment base is not as up to date as one might like, but it still represents an impressive capability for undertaking new space projects.

The space station: an attractive prospect

Although others have suggested a variety of objectives for NASA in the coming years, the organization itself has chosen to propose a space station as its next major project. What remains to be decided is whether the nation wants to use NASA's capabilities for such an enterprise.

The notion that a manned orbital facility of long duration is an essential element in the development of a national space capability has been around for more than 25 years; what has changed over time is the reason given for why such a facility is essential. The current rationale is mixed: the station is seen both as a research and development laboratory for exploring scientific questions and technological potentials and as an operations center involved with on-orbit assembly, testing, deployment, orbital transfer, data processing, and spacecraft servicing and storage. This rationale describes the station and the long-

duration presence of humans in orbit as elements of a space "infrastructure"—that is, the supporting capabilities required to accomplish various missions and objectives. There is even a willingness again to talk of the space station as a crucial step in the manned exploration of the solar system.

Developing a space station is an attractive prospect to NASA for a number of reasons. First, it may be the only major new program on the horizon that has a reasonable chance of Administration and congressional backing. Second, it would keep usefully occupied those technical staff members of NASA who are winding up their work on the shuttle. Third, a station fits into the current concept of an appropriate undertaking for the space agency: it is a means to multiple ends, not an end in itself. In a sense, a NASA space station project aimed at serving all those interested in operating in space is a bullish approach to creating a long-term partnership of the public and private sectors for space exploitation—but this approach will work only if NASA also changes and becomes an effective partner to the private sector. Whether or not NASA gets the go-ahead sign for the space station, it is clear that a major theme of the nation's space policy through the next decade will be the creation of such a partnership.

NASA's role in helping private enterprise

The Reagan administration's space policy announced last year gives equal weight to preserving "United State leadership in critical space activities" and providing "a climate conducive to expanded private sector investment and involvement in space activities." A recent National Academy of Public Administration report called for NASA to make a "major commitment to the commercialization of space technology," a commitment that would require a much more intimate relationship between NASA and U.S. business than has existed historically.

For NASA to be an effective partner of private enterprise in space, a substantially different organization from that which now exists—and probably some significant changes in NASA's authority to engage in joint public-private activities—will be needed. Business analysts and cost accountants will have to join engineers on the NASA staff, and the agency's R&D priorities will have to be based as much on the advice of industry and other users of space as on the next interesting technological problem. It will be hard to maintain the astronaut-as-hero image when a corporation booking a major share of the space on a shuttle flight can nominate someone to ride along with the payload, as the McDonnell Douglas Corp. has done already.

Although NASA has made an honest effort in the last few years to assist those who see a potential for profitable investments in space and to reduce the risks associated with such investments, this role still appears to be assumed grudgingly. This will have to change if one of NASA's roles is to provide the foundation for private entrepreneurs who wish to exploit space technology.

Routine use of outer space as a place to work will not have the pizzazz of lunar and planetary exploration. In this environment, NASA will be only one, and not necessarily the dominant, U.S. actor in space. What NASA does best is research and development in space technology and demonstration of the feasibility of various space systems. Other Government agencies and other private-sector organizations are likely to emerge as the operators of those space systems, whether they be launch vehicles, earth-observation spacecraft, space factories, or communications satellites. National space activities in the next quarter century will not be dominated by NASA anywhere near to the degree they have been in the past.

Competing with Europe and Japan

At the same time, the United States will be only one among many nations in the world with a sizable space effort. A major finding of a recent U.S. Office of Technology Assessment study of space policy was that "unless the United States is prepared to commit more of its public and private resources to space than it does now, it will lose its preeminence in space applications during the 1980s. Both technological and commercial leadership are at stake," the study noted.

The U.S. space program of the 1960s was shaped by strategic political competition with the Soviet Union; the program of the 1980s and 1990s may be as strongly influenced by economic competition with Europe and Japan. The Academy of Public Administration recognized "the constructive and catalytic role space efforts can play in sustaining the technological and economic competitiveness of large sections of American industry."

If space becomes a major arena of international economic competition, then NASA's R&D efforts will have a higher priori-

38-036 O - 84 - 6

ty than they do now and more of the agency's technical capabilities will be engaged in economically oriented efforts. Other advanced countries, particularly France and Japan, seem to have identified space technology as one of the underpinnings of economic success several decades from now, and these nations are making the early investments required to assume a leading role in space.

By its actions two decades ago in creating NASA and seeking space preeminence, the United States got a head start in the race to create payoffs from space; the decision to develop the space shuttle sustained this leading position. If the benefits of past investments are to be realized in the next 25 years, a NASA—and a nation—much more oriented to technological and economic benefits and more sensitive to besting its international competitors must evolve, almost certainly requiring a close conjunction of the leading sectors of U.S. business and the Federal government.

Merging with the military?

The U.S. space program now includes an increasingly large military effort with its own objectives, budget, and institutional structure. There has been a much greater recognition of the strategic importance of space by the top management of the Department of Defense and the Air Force. Increasing militarization is the most important space development of the last decade. This article does not address military space activities in great detail, although they could well become the dominant part of the Government's involvement in space. As the militarization of space continues, NASA will certainly be called upon to provide R&D support, but the Department of Defense is likely to keep most of its space-related activities in-house. However, if NASA does not develop strong links with the private sector, the agency eventually could be swallowed up by the Department of Defense. Control over staff and facilities would then be transferred from civilian to military authority.

There are substantial political arguments for maintaining a separate civilian space agency even if the growth of the military program continues. There are benefits to be reaped from the ability to engage in international scientific cooperation and economic competition, to use NASA programs and representatives as symbols of positive national achievements, and to conduct an open U.S. space program while at the same time continuing a classified national security effort. Merging NASA and DOD space efforts would mean losing those benefits.

An uncertain future

It is possible, on the basis of recent trends, to conclude that NASA, as a unique experiment in developing a new technological sector by a civilian agency of Government, is winding down; that the institution is fast fading from neglect, misuse, and militarization; and that it could not effectively mobilize the resources to meet a new external challenge.

Another possibility, however, is that NASA will not receive a new systems-development assignment such as the space station; instead, it will obtain the resources needed to maintain itself as an R&D agency with modest science and application efforts. Such an organization would be much leaner, make fewer headlines, and have less political visibility, but it still could be quite effective in achieving important objectives.

Perhaps the most desirable option is for NASA both to remain a large and capable R&D organization and to evolve into an effective partner of private-sector space interests. It is highly unlikely, however, that NASA will ever reemerge as the kind of highly mobilized entity it was during the Apollo era. For the last 25 years, NASA has served this nation well; unless the United States turns away from space in the next 25 years—and this is not likely—it is probable that NASA, shaped by an exciting adolescence but adjusting to the more restrained expectations of adulthood, will continue to serve the United States well in the years to come. ◆

SPACE TOMORROW: THE ANTARCTICA MODEL

The people of the United States are, by both history and inclination, pragmatic and practical. Yet they have always been a people with a vision. Some have called this vision simple and sometimes naive. Yet it is that vision that has so often led the United States to dare and achieve. Americans have been pathfinders, farsighted enough to set goals and sights on points beyond, yet imaginative enough to figure out how to reach them.

The U.S. approach to opening space, the last and greatest frontier, has been solidly grounded in the American experience. It has relied on realism, imagination, vision, daring and, in Alexis de Toqueville's words, "the strength and reason of the individual."

Americans have never shirked reality, with all its dangers and all its opportunities. And perhaps that is why the United States stands now on the threshhold of what will surely be a magnificent new era in space. Those who will reap the rewards of that era will be those, who, as Pericles once said, have the clearest vision of what is before them, glory and danger alike, and, notwithstanding, go out to meet it.

If the past is any guide, the United States will be in the forefront of that great adventure. It will go forward with those who share its vision of the future.

NASA's contribution to technology

The National Aeronautics and Space Administration, the agency that spearheaded the nation's achievements in space, is now celebrating its silver anniversary. Since 1957, when Sputnik's faint beep-beep from space shocked the United States into affirming its national pride, resulting a year later in the creation of NASA, the agency has been the driving force in maintaining U.S. preeminance in space and aeronautical technology. Indeed, NASA has played a vital role in stimulating new technology development across the board. And in doing so, it has helped build national economic strength at home and competitive strength abroad.

Whole new industries, such as computer science, solid-state electronics, medical electronics, and communications satellites were advanced largely as a result of NASA's research and development activities. New jobs and economic growth have sprung from U.S. investment in high technology. Technology drives the United States.

And it also drives the rest of the world. The Europeans and the Japanese are developing high technology that rivals U.S. expertise. And with it has come the entry of these nations into space. The Soviet Union has an impressive space capability. Brazil, India, Indonesia, the People's Republic of China, Canada, and

James Beggs
National Aeronautics and Space Administration

others have entered the space arena. And the list of countries who view space as essential to their activities on Earth is growing longer every day.

Small wonder, then, that when the editors of *Spectrum* asked me to write this piece on where the space program will be in the year 2008, NASA's golden anniversary year, two obvious considerations came immediately to mind. They were the growing number of spacefaring nations and the increasingly international aspect of space activities.

Internationalism in space's future

Looking another 25 years down the road, I believe these two factors clearly indicate that we are entering a new era of truly international cooperative ventures in space.

My friend, the late Wernher von Braun, was both a visionary and a pragmatist. He foresaw this trend. When speaking of the future of mankind in space, he used to draw an analogy between the exploration of Antarctica and the exploration of space. I don't know whether his analogy is valid. But I believe it serves as a useful philosophical framework for thinking about the future in space.

Dr. Von Braun pointed out that Antarctica and space have three things in common. Both are far away and hard to reach. Both are hostile to human life. And both require complex logistical planning and operations if people are to get to their destinations and survive.

Expeditions to the South Pole by the Norwegian Roald Amundsen in 1911 and the British explorer Robert Scott early in 1912 were carried out for reasons of national prestige, not unlike our Apollo program.

But permanent settlements in Antarctica came about only because of the dawn of a new technology, that of the airplane, in the late 1920s. By then aircraft had become reliable enough to be used for long flights over very hostile territory.

With planes it became possible not only to map the huge island continent, but also to supply and resupply bases with equipment and supplies and to rescue people, should that be necessary. Today the ice of Antarctica is dotted with permanent bases built by many nations, all dependent for their survival primarily on the use of aircraft.

What are the enabling technologies that would bring us back to the moon, or to Mars, or to the asteroids, to explore at first, and later, perhaps, to establish permanent bases? Clearly, they would have to be those technologies that would be part of a permanent earth-orbiting space base and the orbital-transfer vehicle that could be developed with it. An orbital-transfer vehicle is a rocket based at a permanent space base in orbit. Together with lunar landing vehicles, it could make possible further manned exploration of extraterrestrial bodies.

With the U.S. Space Shuttle the United States stands on the verge of realizing one of mankind's oldest dreams, building a permanent manned space base in orbit and, from there, charting pathways to the planets and the stars.

Back to the moon

I firmly believe that, if such a base were in orbit by the year 1991, the United States would be back on its way to the moon by the year 2000. And by 2008, when NASA will be 50 years old, other nations will have joined in this endeavor, as they have joined in the exploration of Antarctica.

We are fortunate indeed to live in an age of great adventures. The 1920s and 1930s saw the exploration of the polar regions of the earth. In the 1940s and 1950s the exploration of the depths of the ocean began to bear fruit. Humankind is now embarked on the greatest adventure of all: the exploration of the solar system, the galaxies, and the universe.

This enterprise will not only occupy the human race for centuries to come, but it could also very well serve as the catalyst for peaceful cooperation and true brotherhood for all the nations of the world.

The challenges and opportunities are boundless. If we are confident, bold, and determined not to let them pass us by now or in the future, the bounties could dwarf those of all previous eras of exploration combined.

Arnold Toynbee once wrote that "civilization is a movement and not a condition, a voyage and not a harbor."

Since the dawn of civilization we have traveled a long road. But, to paraphrase Robert Frost, we have miles to go before we sleep. In the face of cosmic forces, human beings have embarked on a voyage that has already achieved astonishing things. We have done so through sheer force of will, with courage and with faith in the future.

If we continue in that spirit, I have every confidence that we will, one day, extend our reach to the stars. ◆

- *Cosmic Discovery: The Search, Scope, and Heritage of Astronomy*, by Martin Harwit, Basic Books, New York, 1981, a general reference to discoveries of phenomena throughout the universe.

A number of groups can provide general and specific material about space. The Planetary Society, for example, was formed to encourage planetary exploration. It can be contacted at P.O. Box 91687, Pasadena, Calif. 91109.

The IEEE Aerospace and Electronic Systems Society holds meetings and conferences and exchanges information with experts in such fields as flight instrumentation, electronic ground-support systems, and satellites. For more information, write the IEEE Aerospace and Electronic Systems Society, 345 E. 47 St., New York, N.Y. 10017.

Particularly helpful is the American Institute of Aeronautics and Astronautics, a nonprofit society of engineers and physicists in the aerospace business. It holds meetings and publishes *Astronautics and Aeronautics*, a monthly magazine covering current topics in the field. Its executive branch office is at 1633 Broadway, New York, N.Y. 10019; phone 212-581-4300. The AIAA library, Technical Information Services, has literature on aerospace activity at 555 W. 57th St., New York, N.Y., 10019; telephone 212-247-6500. New material from the library is published semimonthly in the *International Aerospace Abstracts*.

The Video Vision Association produces laser video disks about specific NASA launchings including the U.S. Space Shuttle, the Voyager, and the Apollo missions. The disks contain film clippings and diagrams covering all aspects of the missions. Obtainable from the Association at 37 E. 21st St., New York, N.Y. 10010, they are produced by the center of Aerospace Education at Drew University, Madison, N.J. 07940.

1. CROSSROADS IN SPACE

Humanization: man or machine?

Two informative NASA technical memorandums on automated space activities are "Self-Replicating Systems—A Systems Engineering Approach," by Georg von Tiesenhausen, July 1980, and "Management and Control of Self-Replicating Sysems: A Systems Model," February 1982, by Dr. von Tiesenhausen and Wesley A. Darbro.

For a detailed analysis of the political implications of landing on the moon, see *The Decision to Go to the Moon: Project Apollo and the National Interest*, by John M. Logsdon, Chicago University Press, Chicago, 1976.

Militarization: peace or war?

The New High Ground, by Thomas Karas, describes the increasing use of space for military operations [see Book Reviews, p. 9].

Transcripts of the hearings on arms control and the militarization of space, which took place before the U.S. Senate Committee on Foreign Relations' Subcommittee on Arms Control, Oceans, International Operations, and Environment on April 14 and May 18, 1983, can be obtained from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

An environmentalist's view of the threat of the militarization of space is given in a paper, "Global Geopolitics" by Daniel Duedney, Worldwatch Institute, 1776 Massachuetts Ave., N.W., Washington, D.C. 20036, 1983. See also his booklet *Space: The High Frontier in Perspective*, Worldwatch Paper no. 50, August 1982.

For the Department of Defense booklet, *Soviet Military Power: 1983*, with a preface by Defense Secretary Caspar W. Weinberger, write the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Two volumes prepared by SIPRI (Stockholm International Peace Research Institute) are major references on technology of space warfare: *Outer Space—Battlefield of the Future?*, 1978, and *Outer Space—A New Dimension of the Arms Race*, 1982. Both can be obtained through Crane, Russak & Co., 3 E. 44th St., New York, N.Y. 10017.

Internationalization: harmony or tension?

For information on the Soviet space program, see the Senate Committee on Commerce, Science, and Transportation's report entitled *Soviet Space Programs: 1976–1980*, U.S. Government Printing Office, Washington, D.C. 20402, 1982. The report covers supporting vehicles and launch vehicles, political goals and purposes, and international cooperation in space.

A technical memorandum summing up reports of an OTA workshop and covering internationalization, space applications, UN treaties, and militarization is *Unispace '82: A context for in-*

ternational cooperation and competition, Office of Technology Assessment, Washington, D.C. 20510.

The United Nations periodically publishes pamphlets on the affairs of the Committee on the Peaceful Uses of Outer Space, available from the Office of Public Information, United Nations, N.Y. 10017; telephone 212-754-1234.

For more information on past and current cooperative space efforts, see *Space activities of the United States, the Soviet Union, and other launching countries/organizations: 1957–1982*, prepared by the Congressional Research Service and based on research by Marcia Smith of the Library of Congress. Write the U.S. Government Printing Office and request document no. 19-550-0.

Commercialization: high time for profits?

The present state and possible future directions of satellite communications, land remote sensing, materials processing in space, and space transportation are evaluated in *Civilian Space Policy and Applications*, compiled at the request of the Senate Committee on Commerce, Science, and Technology and available from the Government Printing Office.

EOS (for electrophoresis operations in space), a description of the McDonnell Douglas materials-processing experiments, can be obtained from the McDonnell Douglas Astronautics Co., St. Louis Division, St. Louis, Mo. 63166; telephone 314-232-0232.

Space Business News, a publication devoted exclusively to the business use of space, is published twice a month at 1401 Wilson Blvd., Suite 1000, Arlington, Va. 22209.

The economic benefits of the space program are discussed in *Space Benefits: The Secondary Application of Aerospace Technology in Other Sectors of the Economy*, prepared by the program for Transfer Research and Impact Studies, Industrial Economics Division, Denver Research Institute, University of Denver, Denver, Colo. 80210.

2. SPACE TECHNOLOGY

A monthly magazine that gives recent developments in telecommunications is *Satellite Communications*, 6430 S. Yosemite St., Englewood, Colo. 80111; telephone 303-694-1522.

The future of remote sensing is discussed in Vols. I and II, 1982, of the IEEE digest of *1982 International Geoscience and Remote Sensing Symposium*, IEEE, 345 E. 47th St., New York, N.Y. 10017.

"Technology components of solar arrays for space platforms," a paper delivered by Klaus Bogus of the European Space Agency at the Sixteenth IEEE Photovoltaic Specialists Conference in 1982 in San Diego, Calif., assesses current space photovoltaic technology activities in Europe related to future space platforms. During the same conference, John S. Monck of the Jet Propulsion Laboratory in Pasadena, Calif., presented "New Directions in Solar Array Development." The conference proceedings, IEEE publication no. CH 1821-8, is available for $54 for members, $108 for nonmembers, from the IEEE Service Center, 445 Hoes Lane, Piscataway, N.J. 08854; telephone 201-981-0060.

Difficulties and differences early in the space program, especially with respect to "man-rating," are outlined in NASA's sp-4201, *This New Ocean: A History of Project Mercury*, by L.S. Swenson Jr., J.M. Grimwood, and C.C. Alexander, available from the U.S. Government Printing Office, Washington, D.C. 20405.

By 1972, when design of the shuttle began, its program-management aspects were well established; they are described in "Space Shuttle Orbiter: A Reliability Challenge and Achievement," by V.P. Ostrander in the 1982 proceedings of the Annual Reliability and Maintainability Symposium, pp. 468-73, available from the IEEE Service Center at the above address.

Methods for reliability designing of spacecraft are given in "Lessons from NASA," by Walter C. Williams, *IEEE Spectrum*, Vol. 18, no. 10, October 1981, p. 79.

3. THE POLITICS OF SPACE

For a more complete picture of foreign space policy, see *International Cooperation in Space*, by Arnold W. Frutkin, Prentice-Hall Inc., Englewood Cliffs, N.J., 1965.

Specific information on space law can be found in the Senate Committee on Commerce, Science, and Transportation's three-volume set of *Space Law: Selected Basic Documents*, second edition, U.S. Government Printing Office, Washington, D.C. 20402. See also the *Journal of Space Law*, published by the University of Mississippi Law Center, University, Miss. 38677.

An overview of international space law is given in *The Modern International Law of Outer Space*, by Carl Q. Chrystol, Pergamon Press, Elmsford, N.Y. 10523.

Readers can obtain a copy of "Activities in space, a matter for international regulation," by Robert W. Buchheim, in the January 1983 *Vital Issues*, by writing to the Center for Information on America, Washington, Conn. 06793. The center is a nonprofit, nonpartisan educational corporation.

Questions regarding the French space program should be directed to the Centre National d'Etudes Spatiales, 129 Rue de l'Universite, Paris 75007, France.

Information on the European Space Agency (ESA) can be obtained from Agence Spatiale Europeene, 8-10, rue Mario-Nikis, 75738 Paris Cedex 15, France, or from its Washington office at Suite 1404, 955 l'Enfant Plaza, S.W., Washington, D.C. 20024.

4. THE FUTURE OF SPACE

To find out what NASA has planned for the next 20 years, see *Planetary Exploration through the Year 2000—A Core Program*, part one of a report by the Solar System Exploration Committee of the NASA Advisory Council, 1983, U.S. Government Printing Office, Washington, D.C. 20402.

Gerald K. O'Neill, a professor of physics at Princeton University, has written two books on space colonies, space manufacturing, and their future prospects: *The High Frontier*, Anchor Press Doubleday, New York, 1982, and *2081: A Hopeful View of the Human Future*, Simon & Schuster, New York, 1981. ◆

Megna/Comsat; [3] The politics of space—A NASA artist's depiction of the planned International Solar Polar Mission; and [4] The future of space—The Galileo orbiter releasing its atmospheric probe designed to make the first measurements of Jupiter's atmosphere, in a NASA artist's conception of a planned 1986 mission.

ABOUT THE AUTHORS

James M. Beggs is the administrator of the U.S. National Aeronautics and Space Administration. Prior to the middle of 1981, he was the executive vice president and a director of General Dynamics Corp. in St. Louis, Mo., which he joined in 1974. Dr. Beggs previously worked for NASA from 1968 to 1969 as associate administrator of the Office of Advanced Research and Technology.

Robert W. Buchheim is a consultant to the U.S. Arms Control and Disarmament Agency. He was the manager of the U.S. delegation negotiating the Treaty on Peaceful Nuclear Explosions and chairman of the interagency study group leading to the U.S.-USSR initiative on a convention on radiological weapons. During President Jimmy Carter's administration, Ambassador Buchheim led the U.S. delegation at the antisatellite (ASAT) talks with the Soviet Union. He has also been the U.S. commissioner on the U.S.-USSR Standing Consultative Commission, which considers complaints of one country against the other.

Hubert Curien is the president of the Centre National d'Etudes Spatiales (CNES), the French equivalent of NASA. He is also the chairman of two international associations: the Council of the European Space Agency, in Paris, which associates 11 European countries for the development and building of launchers and satellites, and the European Science Foundation, in Strasbourg, France, which is a federal group set up through the consensus of 40 research centers located in 16 European countries. Dr. Curien is a full professor at the University of Paris where his research addresses the study of soiid matter.

Robert A. Frosch (F), vice president in charge of the General Motors Corp.'s Research Laboratories in Warren, Mich., heads a science team engaged in applied research and development, long-range research, and specialized-service work for other GM units. For three and a half years, he was a NASA administrator, after which he became president of the American Association of Engineering Societies, the engineering society umbrella organization.

Arnold W. Frutkin, currently assistant to the president of the International Group of Burroughs Corp. in Detroit, Mich., headed NASA's international-relations office for almost 20 years. From 1977 to 1979 he served as the associate administrator of external affairs for NASA and from 1959 to 1977 as assistant administrator of international affairs. From 1962 to 1976, he served intermittently as U.S. Representative to the United Nations Committee on Outer Space Affairs.

John H. Glenn Jr. was elected to the U.S. Senate in 1974 and reelected in 1980. He serves as a member of the Foreign Relations Committee, Governmental Affairs Committee, Special Committee on Aging, and the Senate Democratic Policy Committee. Mr. Glenn, in the initial group of seven men chosen to be astronauts, became the first U.S. citizen to orbit the earth on Feb. 20, 1962, in the Mercury-Atlas 6 "Friendship 7," and assisted in the design and development of Project Apollo.

S. Neil Hosenball has been NASA's general counsel since 1975 and was deputy general counsel from 1967 to 1975. Earlier he was assistant general counsel for procurement matters and worked for four years at the NASA Lewis Research Center in Cleveland, Ohio, as its chief counsel. From 1970 to 1979, Mr. Hosenball was a member of the U.S. delegation to the United Nations Committee on the Peaceful Uses of Outer Space.

George A. Keyworth II was appointed the director of the Office of Science and Technology Policy in the Executive Office of the President in 1981, where he is science advisor to the President. Specializing in nuclear physics, Dr. Keyworth previously was head of the experimental physics division at Los Alamos, N.M., which consisted of several hundred scientists and technicians whose work encompassed basic research in nuclear and fundamental interactions, condensed matter research, astrophysics, space sciences, and applied research toward satellite-based verification of compliance with nuclear test treaties and the physics of superhigh-energy densities.

John M. Logsdon has occupied the space history chair at the National Air and Space Museum of the Smithsonian Institution for the past year. In the fall, he will return to George Washington University in Washington, D.C., where he is director of the Graduate Program in Science, Technology, and Public Policy and professor of political science and public affairs. His research interests include space policy, the structure and process of government decision making for research and development programs, and international science and technology policy. An active member of the American Institute for Aeronautics and Astronautics, Dr. Logsdon has been a consultant to the United Nations, the National Science Foundation, Department of Commerce, Office of Technology Assessment, Environmental Protection Agency, Intelsat, and other public and private organizations.

Theodore R. Simpson (SM) has more than 22 years of experience in the aerospace industry, having worked in the U.S. space program and the air-traffic control system. Currently, he is the project leader at ANSER (analytical services), a consulting firm, where he is doing long-range planning for the U.S. Air Force space program. He contributed to the development of the U.S. Air Force Space Plan and at the present time he is helping to define the military uses for a space station. During 1981, he was an IEEE Congressional Fellow and served on the staff of the Senate Subcommittee on Science, Technology, and Space, where his responsibilities included covering the civilian space program for the subcommittee.

Acknowledgements

The broad range of this special issue and its long time in gestation meant that *Spectrum* editors called on more than 200 experts for advice and counsel. Some became authors, many became sources, still others became reviewers, and no small number labored valiantly to be all three. The list below attempts to thank some of the people without whom we could not have produced this issue. But the issue editor wishes first to make special mention of one of them, David Williamson, who played a very special role in pointing us in the right direction at every step as we put the issue together. Among the others (excluding expert authors listed above) were Tony Calio, Ralph Chipman, Sajjad Durrani, Freeman Dyson, Burton Edelson, Derrick Elliott, Jerry Grey, Paul Hanle, James Hartinger, Richard Henry, Noel Hinners, Martin Horwit, Diana Hoyt, George Low, Hans Mark, John McLucas, Ahmed Meer, Wilfred Mellors, James Morrisson, Bruce Murray, Thomas Paine, Jesco von Puttkamer, Simon Ramo, Eberhard Rechtin, Victor Reis, Harold Rosen, Alex Rowland, Irwin Shapiro, Paul Slee, Willis Shapley, Marcia Smith, Norman Terrell, John Townsend, Len Weiss, Walt Williams, Ray Williamson, and Monte Wright.

Included in this listing are experts who reviewed one or more articles and have given us permission to identify them. Their listing does not mean they necessarily endorse any given viewpoint expressed.

SPACE 2020

THE TECHNOLOGY, THE MISSIONS LIKELY 20-40 YEARS FROM NOW

By ROBERT F. BRODSKY
TRW Space and Technology Group

and BERNARD G. MORAIS
Lockheed Missiles & Space

▲Power System Platform from TRW could have two Spacelab modules to house a crew of four for 90 days between resupply

In two decades space activities have become an accepted and integral part of the lives of a large fraction of the Earth's people and vitally affect the remainder. No one could predict in 1960 the twenty years in space that have just passed, and it is impossible to predict the next twenty. Since those years will determine what happens thereafter, the years 2000 to 2020 are certainly beyond present conception. This report does not attempt to predict what will happen in space, but helped by the insight of almost fifty space-dedicated professionals selected for both their technical expertise and breadth of viewpoint, it sets out what could happen.

Technology 20-40 years from now (T-1) will give us spacecraft electrical plants supplying up to 3000 kw, space structures as long as 400 m on a side, positioning to within 1 m in orbit, communications at rates above 10^3 Mbits/sec, and systems able to operate untended for up to 20 years—30 years perhaps in the case of proto-colonies.

Considerable planning has already been done by government agencies and others for the period leading up to the decades of interest. Many of the programs projected for this period have been approved, and progress for the most part will likely be evolutionary and in accordance with present trends.

U.S. domestic communication satellite capacity is equivalent to 150 36-MHz transponders (or 150

Copyright © 1982 by the American Institute of Aeronautics and Astronautics

color TV channels). This represents approximately 672 voice channels. Traffic is projected to need over 800 channels by the mid-1990s (F-1), when satellites will carry approximately 13% of domestic communications. The introduction of high frequency (30/20 GHz) technology would permit increasing capacity to 2352 channels or about 25% of projected communication requirements in 2000.

Frequency reuse techniques would further increase possible satellite capacity to over 4000 channels by 2020. This capacity roughly matches both projected satellite communication requirements and overall domestic communication requirements. These developments will avoid overcrowding the geosynchronous orbit, where the number of spacecraft has grown consistently at 24% per year.

After the Space Shuttle and its early growth versions, attention will probably focus on Shuttle-derived launch vehicles. New orbital transfer vehicles (OTV) will be needed in the 1990s.

Large space system missions using these launchers in 1980-2000 may include many new commercial and government space applications (T-2, F-2).

A considerable number of technically low-risk missions could be carried out in this period (T-3). Some higher-risk applications may be exploited if needs are strong enough. Most of the riskier missions will for the most part remain in development into the next century.

The basic physical research programs and experiments conducted in near-Earth space from 1981 to 1999 will take advantage of nearly zero gravity (10^{-5} to 10^{-6}g), pressures below any Earth laboratory vacuum, and the absence or reduction of terrestrial disturbances produced by such sources as the atmosphere, ionosphere, Earth vibrations, or radio signals. Representative experiments of basic importance using these and other orbital properties include zero-gravity fluid dynamics, plasma physics, and relativistic clock experiments.

Much more astronomy and astrophysics research in space will evolve from the Space Telescope, Space Infrared Telescope Facility, solar optical and ultraviolet telescopes, spectrographs and coronagraphs, and X-ray and gamma-ray detectors to be carried on or launched by the Shuttle beginning in the 1980s. By the 1990s, an optical telescope of 3-4-m aperture is expected to be tended by man visiting from a nearby low-Earth-orbit (LEO) base.

Solar system exploration in the 1980s and 1990s (F-3) after the approved 1984 Galileo Jupiter orbiter and probe may slowly expand to include:

- Mercury orbiter, about 1989; Mercury lander, about 1993.

Man will have begun to exploit the solar system and will be poised to explore the galaxy beyond it

- Venus orbiting imaging radar, 1986-88; Venus soft lander, 1988-1990.
- Mars surface rover, mid-1990s.
- Saturn orbiter and probe, about 1988.
- Neptune flyby (Jupiter gravity assist), late 1980s.
- Landers on Titan and one or more of the Galilean satellites of Jupiter, such as Ganymede, mid- to late 1990s.
- Lunar orbiter, mid-1990s (primarily to update lunar characteristics in preparation for a manned landing in 2000 to 2005).
- Halley's Comet fast flyby, 1985; comet rendezvous, 1988 to 1990.
- Asteroid flyby, early 1990s.

If Galileo is cancelled, the above missions may be delayed or dropped.

NASA has drawn up unapproved plans for exploring the solar system between now and the end of the century. The plans sketched above map a fairly slow, but steady pace of unmanned missions over the next two decades, which will include detailed investigations of comets, imaging radar mapping of Venus, solar missions, detailed investigations of the Jupiter and Saturn systems, and finally a detailed geochemical/geophysical mapping of Mars, followed by the return of samples from Mars near the turn of the century.

The timing for a Saturn mission coincides with a series of Jupiter swingby opportunities to Uranus, Neptune and Pluto. A decision might be made to take advantage of the opportunity to complete our reconnaissance of the solar system and to delay the detailed Saturn investigation.

Notably absent from present NASA planning is a return to the Moon's surface, although a joint mission with the European Space Agency to perform geochemical and geophysical mapping of the Moon from orbit is a good possibility. In any case, a lunar orbiter should be flown in the late 1990s in preparation for manned lunar activity in the first decade of the new century.

The official plan should probably be viewed as middle of the road. Fiscal restrictions may kill the relatively ambitious missions in it. Reconnaissance missions to Earth-approaching asteroids or inner

main-belt asteroids may then survive along with missions to both the inner and outer planets substantially reduced in scope. Such missions may carry one or two experiments rather than the broad multidiscipline investigations now envisioned.

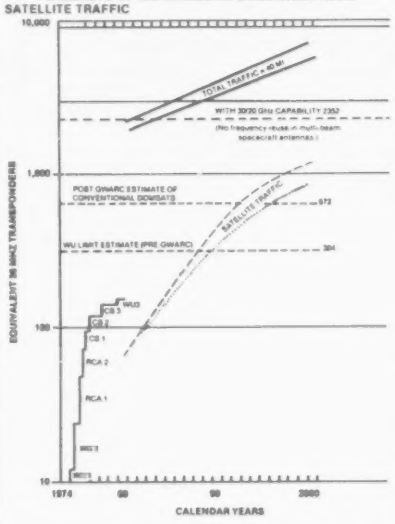
In general, the goals discussed could be reached with current or near-future technology. Development of high-energy propulsion technology would help. Electric propulsion, which has application to asteroid and comet missions, Mercury orbiter, and some outer planet missions, would be nuclear-powered rather than solar. Solar sailing may be used in some missions. Planetary exploration will exploit the ability of astronauts on the Shuttle to add an Inertial Upper Stage (IUS) or a more powerful OTV to a spacecraft already in Earth orbit. Atmospheric braking at the planets will conserve propulsion fuel.

Once the Space Transportation System (STS) becomes operational, full attention must be given to space stations. The Soviets have mounted a clear and substantial challenge, although they still depend on expendable launchers. Attention in the U.S. seems to be turning to an early permanently manned facility in low Earth orbit and a later one in geostationary orbit.

A NASA conceptual program plan leading toward the development and understanding of large space structures (F-4) makes full use of the Shuttle in deploying and constructing typical large structures such as antennas and platforms.

Military space vehicles for observation, communication, and navigation will probably improve at the present rate during the next twenty years, and some

F-1 FORECASTS OF U.S. DOMESTIC COMMUNICATIONS SATELLITE TRAFFIC



new space weapons may appear. Space defense and operations will surely be very active but depend much less on technology than on world politics for their impetus.

Military spacecraft are expected to ride the Shuttle into LEO on the way to their eventual orbits and sometimes to sortie from the Shuttle.

HOW THIS REPORT CAME ABOUT

In the summer of 1980, at President Carter's request, the National Academy of Sciences formed a special committee to study the feasibility of the Solar Power Satellite (SPS). The committee requested the AIAA to set the stage quickly for them by visualizing the state of space technology in 2000-2020 if the SPS were not undertaken. Then AIAA President Artur Mager asked then Space Systems TC Chairman Richard Kline of Grumman Aerospace to organize his committee to reply to the request. This effort was started by an ad hoc subcommittee in August 1980 under the direction of consultant J. Preston Layton.

A 170-page document, dated January 14, 1981, and titled, "Projected Space Technologies, Missions and Capabilities in the 2000-2020 Time Period," resulted. This condensation by two members of the TC attempts to extract the "meat" from the report without losing too much of the flavor.

Scott Dunbar, Space Science Institute; and Robert Salkeld, System Development Corp.

Many of the missions chosen to exploit the numerous military opportunities of the next twenty years (T-4) will clearly carry over into 2000-2020.

Where there is both military and civilian interest, as in ocean monitoring, meteorology, navigation and positioning, and air-traffic control, major programs are expected to be run increasingly as joint ventures to the end of the century and beyond.

Cooperative international programs will grow more common as other nations strengthen their space programs, the ranks of the spacefaring nations swell, and missions become more sophisticated. Missions extending over decades will cost more than one business organization or nation can pay. The variety of talents and skills called for will also argue for international teams.

In recent years in the United States, too little funding has been available for space research and technology development to maintain leadership. Moreover, much of the work has been focused on limited, short-term objectives. Although the wastefulness of unfocused research and unrestricted and premature technology development cannot be denied, the constraints and stingy funding of the past decade may have dangerous consequences. Funding to build the research and technology bases should be strengthened well beyond that presently planned, or the technology available at the start of the 21st Century will be inadequate. This is particularly true for materials for space application.

Determining physical, chemical, and electrical properties, product availability and cost, fabrication characteristics with similar and dissimilar materials, and the effects of aging takes a long time. Work on new materials for the year 2000 must be started very soon. Although some efforts are in progress, much broader and more thorough programs are needed.

ROBERT F. BRODSKY (AF), at left, is a senior systems engineer for TRW Space & Technology Group working on advanced spacecraft and space platforms. From 1971 to 1979 he headed Iowa State University's Aerospace Engineering Dept. Brodsky chaired the Aerospace Dept. Chairmen's Association, and both the AeroSpace Div. and the Technology Assessment Committee of the American Society for Engineering Education. He holds a BSME from Cornell Univ., an MS in aeronautics from NYU, a Master's in applied mathematics from the Univ. of New Mexico, and a Doctorate in engineering from NYU. **BERNARD G. MORAIS** (M) directs system engineering for the Space Systems Div. of Lockheed Missiles & Space. In 21 years at Lockheed he has worked on the Standard Agena, Ascent Agena, a number of launch vehicle programs using the Agenas to launch USAF spacecraft, and an Air Force orbiting vehicle. He chairs the 1982 AIAA/NSIA/USAF Space Div. Military Space Systems Technology Workshop. Morais received a BSEE in 1959 from California State Polytechnic-San Luis Obispo, and an MS in systems management in 1974 from the Univ. of Southern California.

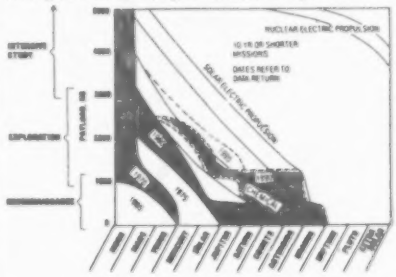
Materials for use in space must be adequately characterized and their production and fabrication techniques must be established, since testing devices under operational conditions for extended lifetimes is very difficult.

Materials should also be screened to find those most likely to be improved by processing in space, and early efforts should be made to develop special characteristics by working them in the extremely low gravity and high vacuum of space. Materials properties quite different from those we are familiar with may result from such research.

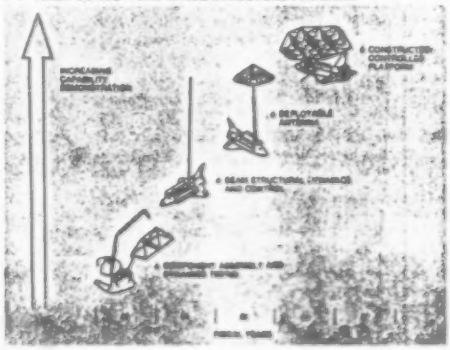
By the year 2000 large structures such as permanently-manned space stations may be in geosynchronous orbit and space factories and housing for space workers may be on the immediate horizon. Placing all that material in orbit from Earth will be expensive. An alternate source of raw materials is the Moon. Processing lunar materials in the vacuum of space will permit using for structures many elements that are not suitable on Earth. For example, the alkali metals can be used as both structural and electrical materials. Sodium has excellent specific electrical conductance. In space the number of materials that can be used directly will more than double, and the number of applicable alloys will increase geometrically. Some of these materials, when properly alloyed, might also prove suitable for use on Earth.

New and more advanced composites will be lighter, stronger, more dimensionally stable, stiffer, have higher temperature resistance, and last longer when used in space. They will be composed of

F-3 SOLAR SYSTEM EXPLORATION MISSIONS
For single Shuttle launch, flight times less than 10 yr.



F-4 NASA CONCEPTUAL SPACE STRUCTURE PROGRAM



T-4 MILITARY OPPORTUNITIES, FEATURES, RELEVANCE, AND KEY TECHNOLOGIES
From Stanley Rosen.

Opportunity (operational time period)	Features	Relevance	Key technologies
Global info/C^3 network (early 70s)	All-source 10^2-10^3 Mbps data trunks Hi/lo data rate tap-off by users on demand Redundant sat-sat links, auto-reconfiguration Smart terminals	Moderate-to-high conflict levels Follow-ons to DSP/SED DSCS III, GPS III, SCF RTS ZI control of theater RPVs Data fusion centers NASA TDRSS, needs Sat. business system Remote sensing system data distribution	On-board data processing Sat-sat links, e.g. laser, V-band Mil spec VHSIC/rapid access memories Terminal design/human interface IR and radar sensors

metal, organic (such as high-temperature polyamides), ceramic and glass matrices and fibers made of organics such as aramids, inorganic non-metals such as graphite, ceramics, and glasses, and metal wires, whiskers, and ribbons.

Materials shipped from Earth to be converted into various structures will be packaged more efficiently. For example, sodium may be used to make electrical conductors. If it were shipped as a hydroxide, it could be disassociated in space into sodium metal, oxygen, and water, all of which would be useful.

Ceramics are receiving attention for aerospace applications because they are well characterized under substantial stress at high temperature. They will find much greater use in devices such as closed Brayton cycle space power systems where temperatures above 1100 K are desired (F-5).

Other materials used in space will include specially tailored plastics and special forms of rare elements and nuclides. Programs for projecting requirements for special materials and testing their properties in space under realistic operating conditions are needed soon to lay a proper foundation for space activities after the turn of the century.

Space structures in 2000-2020 should fall into two distinct categories: pressure vessels and open frames. Pressure vessels are relatively "dense" structures, robust and able to stand some handling abuse. Open frames are generally large and fairly delicate.

Pressure vessels are used for fluid storage, habitation and laboratory modules, and space workshops. They will come in a wide range of sizes. Most will fit within the Orbiter cargo bay (4.5 m diam. × 18 m long). Limited use may be made of specially adapted versions of the Shuttle External Tank (8 m diam. × 47 m long). Giving the empty

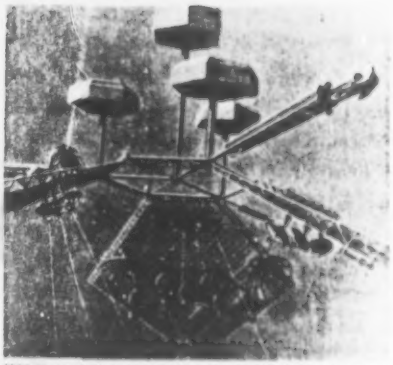
tank a small amount of extra velocity can boost it into a low Earth orbit. There it could serve as a workshop, a large-volume fluid store, or a relatively rigid workbench with a large external area for construction, assembly, or experiments.

Open frame structures are typically used for large antennas and for extended platforms. Antennas for frequencies up to 1000 GHz and with a longest dimension up to 10 km will, for the most part, be fabricated on the ground and unfolded in space. This will hold for all antenna types—reflectors, phased arrays, or hybrids. Antennas will reach 300 m diam. by the year 2000, and 1 km diam. by 2020. They will use composites for compression members and tension trusses to minimize thermal distortion.

Platforms will use three lightweight space framework approaches: ground fabricate/space unfold, ground fabricate/space assemble, and space fabricate/space assemble.

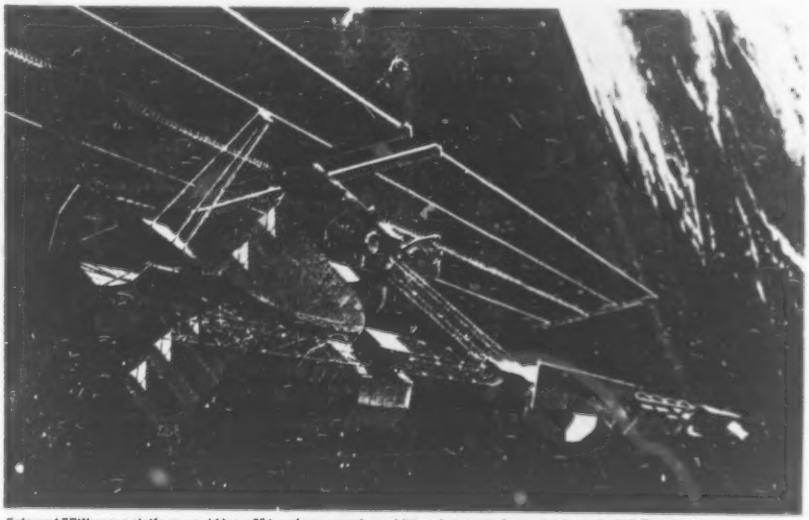
The third method will come into play for only the largest platforms.

A typical platform in the year 2000 will have an area of about 100 m^2 with structural members mostly 5-15 m long. By the year 2020, platforms of 10,000 m^2 will be needed. These could be either ground fabricated/space assembled or space fabricated/space assembled. They will be made of both aluminum and composites.



Military or civilian space station for 2000-2010 from Lockheed would have lasers as either weapons or communications carriers (antenna-like structures with beams). Each of three vehicle docks can accommodate three craft at a time. Central pentagonal structure at top houses control and power equipment and some crew. New segments can be added down the column. Outlying pentagons serve as work stations, have solar cells as a standby independent source of power. All pentagons can be spun to create artificial g. Large bubbles at bottom are OTV hangars. Small ones and tanks at right store propellant. Domes on left gridwork are observatories. Grid is 10 m thick.

Space construction bases will use robots to locate, translate, and rotate large, lightweight thin-sectioned structures, and apply quality control and joint-integrity verification methods, in-space repair methods, and space fabrication machines now called beam builders. Beam builders under development make both aluminum and composite members in sizes that may well satisfy the needs of 2000-2020.



Enlarged TRW space platform would have 25 kw of power and an additional structure for payloads such as VLBI radio telescope.

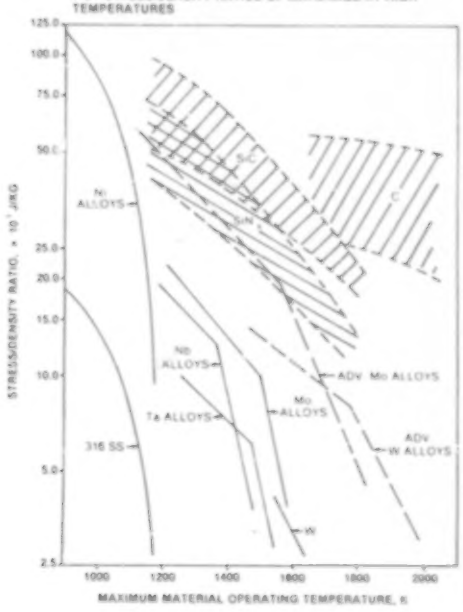
Their use may not be routine by 2000, but will be by 2020.

In space, as in aircraft technology, propulsion advances make things happen. Well before the end of the century, the STS engines will be outmoded and have to be replaced.

By 2000 the IUS and spinning solid upper stages will probably have been replaced by versatile liquid propellant upper stages and by an early version OTV, probably with an improved RL-10 liquid oxygen/liquid hydrogen engine. An advanced OTV, with increased payload and other capabilities, and possibly based on a small space platform, will have been built. Studies and analyses to define the OTV missions and traffic should begin now, in conjunction with space station studies.

Large booster and launch vehicle first stage engines with high density hydrocarbon fuels will be needed around the turn of the century or sooner for Shuttle growth and derivative versions. They will be followed by advanced-technology dual-expander engines using both hydrogen and liquid oxygen as coolants. These engines will be designed primarily for single-stage-to-orbit and heavy-lift vehicles.

F-5 STRESS/DENSITY RATIOS OF MATERIALS AT HIGH TEMPERATURES



Solid rockets burning high energy and hybrid propellants will continue to be developed for special applications, but will be largely replaced by liquid rockets in all but launch boost applications.

Advanced electric propulsion will have been demonstrated on experimental flights and unsophisticated operational missions by 2000. It will have the technology of the present or slightly improved solar/electric propulsion system.

By the early 21st Century the present ion bombardment thrusters will have increased in size from 30 cm to 50 or 120 cm diameter. For many, especially near-Earth, applications mercury propellant will probably be replaced by noble gases or other easily ionizable materials.

Magnetoplasmadynamic (MPD) thrusters are just emerging from the research laboratory, but should be ready for application in 2000-2020. Pulsed and steady-state MPD propulsion promise greater efficiency and simplicity than ion propulsion of higher thrust density without the necessity for neutralizing the exhaust stream.

Other methods of propulsion that may be developed in 2000-2020 include solar sailing, laser propulsion, fusion micro-explosion rockets, and mass driver reaction engines. One interesting concept with great technical challenge and mission potential that is being considered is a matter-antimatter annihilation rocket engine. Means for generating and handling the anti-proton working fluid and other aspects have been studied on paper.

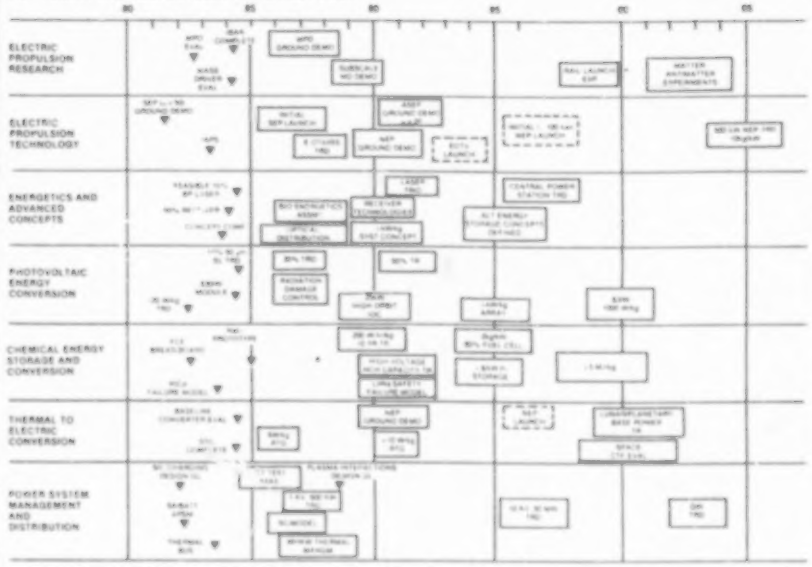
Insufficient electric power has limited the performance of spacecraft. New power systems in the next twenty-five years should remove this restraint (F-6). Many of the items shown in F-6 may be delayed until after the turn of the century, especially nuclear systems and those for higher power.

Research and technology in aerothermodynamics will be directed toward advanced space transportation, planetary exploration, and atmospheric maneuvering vehicles. Technology areas receiving emphasis are flow field computational methods, heat shield materials, and rarefied flow analyses. Certain viscous interaction regimes such as shock-induced boundary layer separation and transition to turbulent flow will continue to receive attention.

Each of the above technologies should have matured by 2000 into practical engineering tools based on sound understanding of their physics, and new topics we cannot predict will have replaced them as subjects of research by 2020.

Active electronic systems will replace passive approaches to structural, altitude, and thermal control to satisfy demands for increased efficiency and performance. Integrating electronics into all critical

F-8 TWENTY-FIVE YEAR OUTLOOK FOR SPACE POWER



components of space systems will call for significantly different design approaches, as we try to make spacecraft completely self-repairing.

All electronic systems in critical applications will have high fault tolerance and adaptability. Loss of function due to random failure or damage will not be accepted. Equipment will incorporate autonomous failure detection, identification, and reconfiguration, and redundant portions that can be called on to permit long-term operation. The electronic systems will be able to adapt to a wide range of changing environments such as those encountered during the construction of a large platform.

Purely electronic systems will dominate sensor technology 2000-2020. Mechanical scanning will be replaced by high density focal plane arrays in the spectra from untraviolet through infrared. Radio frequency (RF) sensors will become increasingly important for Earth observation. Multispectral systems will be based on tunable detectors, some using optical heterodyning. Active optics will give figure control and aperture shaping allowing wide freedom in trading resolution for power (noise). Apertures of hundreds of meters will be used at RF, and figure control will maintain aperture surfaces accurate to within 1/50 of a wavelength or better.

Line-of-sight pointing control will be to submicroradian accuracies for some antennas below 1000 km and for most antennas at synchronous altitude and above. IR and RF sensors will have both active and passive coolers. Passive sensors on a satellite will consume 5-10 kw, and active sensors, 25-50 kw.

Satellites will have large numbers of sensors collecting data at the rate of megabits per second. To keep storage and transmission within reasonable bounds, the satellite will need enough processing capacity to compress sensor output and still extract vital information. Contrary to practice in the '80s, much information gathered by satellites in 2000-2020 will be used in real time on the ground.

Satellites will navigate themselves rather than being tracked and controlled from the ground. They will determine their positions in real time and use that information for control, coordination with other satellites, and processing sensor data. Navigation measurements will be made from astronomical bodies and from groups of satellites positioned for that purpose that will also serve for navigating at sea, on land, and in the air. Spacecraft will locate

38-036 O - 84 - 7

themselves within 1 m or less, and, when rendezvousing or docking, will determine relative positions to an accuracy of 1 cm.

All spacecraft will exercise active control of attitude and configuration to maintain electronic and optical structural integrity, and to control vibration, and pointing. Control bandwidths will extend to the hundreds of Hertz, as structures grow more massive and flexible. The great size of some of the space structures will require a large number of sensors and actuators and a highly distributed data processing architecture. Large structures will have controllers that can keep track of such characteristics as varying gross mass, center of mass, and vibration modes and frequencies, and can adapt to great changes in a structure, as when a platform is being constructed, modules are being added, or OTVs launched or docked.

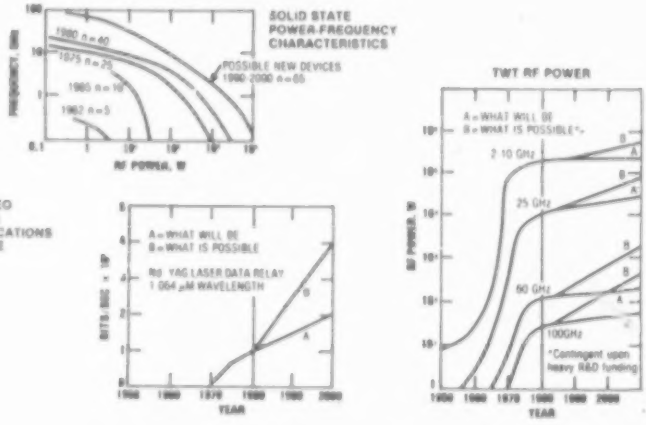
Unmanned OTVs will have active guidance, as will specialized craft for rendezvous and construction vehicles for building a platform. The guidance systems will furnish either minimum-fuel or minimum-time trajectories, having errors determined principally as a result of using the earlier mentioned navigation aids.

Builders of communication and data handling equipment for both civilian and military space use today must tax the state of the art to satisfy customers' desires. Despite making strides during the next forty years, technology will continue to lag behind demands.

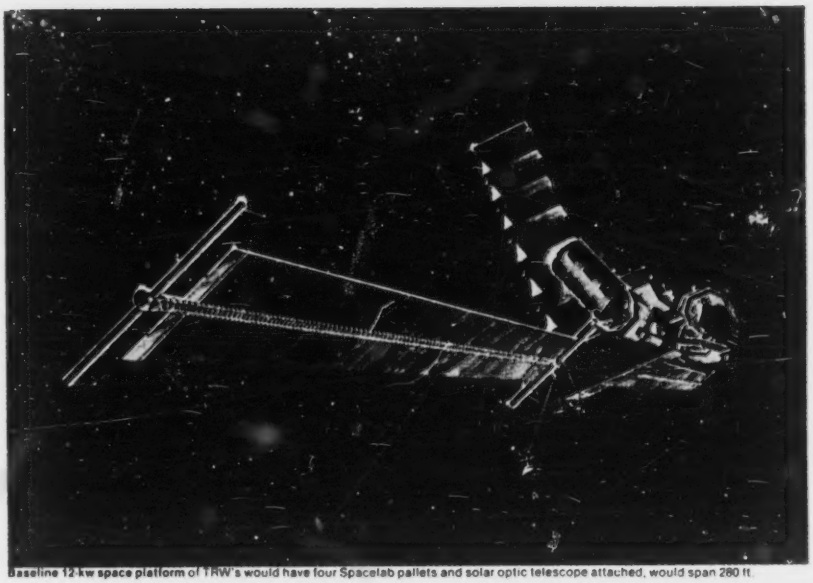
We see this prospect in the ever increasing demand for communications. Space is rapidly filling with satellites and their accompanying interferences. If we were confined to present and near-term technology, demand for service by 2000 would exceed the capacity of the number of satellites that can fit in GEO—120 operating at 12-14 GHz. This squeeze will lead to more and more international control in parallel with the international allocation of broadcast frequencies that began in the 1920s. As indicated earlier, means are available to prevent saturation.

Replacement satellites will operate at higher frequencies, have smaller antenna side lobes, and use beam shaping and polarization techniques. By 2020 large communications structures will have supplanted the satellites we know today. They will use steerable spot beams for communication of broadcast TV and electronic mail directly to users. On-board data processing will permit using the communications paths to maximum capacity.

F-7 COMMUNICATIONS TECHNOLOGY TRENDS INTO THE 21ST CENTURY



Lasers at visible or near-visible frequencies may begin to replace RF for communicating between Earth satellites (F-7). They will be immune to accidental or deliberate radio interference. Coded laser links may also connect spacecraft outside the solar system to a deep space relay station in GEO. Such links will handle adequate imaging data rates from the nearer stars, rates impossible by microwave with foreseeable antenna apertures and power because of its much broader beam. Laser communication will



Baseline 12-kw space platform of TRW's would have four Spacelab pallets and solar optic telescope attached, would span 280 ft.

be used to reduce considerably the size of some spacecraft, but microwave will remain the preferred frequency for Earth links.

Communications technologies that will be developed between now and 2000 and applied in 2000-2020 include:

- Multibeam antennas from 1 to 18 GHz and above.
- Phased array antenna feeds.
- Solid state, traveling wave tube, and field effect transistor (FET) amplifiers.
- General extension of useful RF bands to 40-100 GHz (F-7).
- Lasers for intersatellite and extra-solar system communications.
- Low-cost ground terminals.
- Message switching.

High power solid state transmitters, high-frequency-band operations and large bandwidth channels, large antenna farms (and feeds) for multibeam spot coverages, time division multiple access techniques, and automatic adaptive on-board traffic management will be highly developed by 2000. T-5 estimates the range of communication parameters in the early 21st Century.

The economics of communication satellites and multisensor Earth observation and military surveillance spacecraft in 2000-2020 will dictate data rates on the order of 10^9 bps. Many imaging sensors in this era will generate 10^{11} bits per frame, about 100 times as many bits per frame as 1980 sensors.

For lengthy space missions, especially to the outer solar system, the self-test and repair computer and other fault-tolerance autonomous maintenance approaches will raise the reliability of all systems using computers. Computers will make use of redundancy in such ways as by voting logic, element switching, system reconfiguration, diagnosis in real time, and strategy modification.

On-board decision-making will also allow more

T-5 COMMUNICATIONS TECHNOLOGY IN THE 21ST CENTURY

Parameter	Range

Antenna dimensions	5-30 m diam single reflector 10 m × 50 m array
Beams/spacecraft	Up to 100 simultaneous beams per spacecraft

complicated sequences calling for close cooperation between sensors and actuators.

For most satellites on-board navigators will supply orbital state information to the ground.

Most satellites will supply almost all their own orbital state information to the ground from their on-board navigators. Some, such as navigational support and abandoned satellites and space debris, will have to be tracked. Tracking will be done from the ground and space by radio and laser transponders and radar and lidar. Radar and lidar will be able to track out to geosynchronous orbit.

The tracking system will maintain a precise catalog of debris and inactive satellites and predict operational conflicts or collisions twenty-four hours in advance. This service will be most important to large space structures.

Tracking from the ground will determine position to 1 cm out to geosynchronous altitude for targets with RF or visual cross-sections of 0.1 m^2 or more.

As spacecraft proliferate they will have to be more autonomous if command and control are not to be overtaxed. Few will need individual support. They will share services such as navigation measurement and data relay, and will have a backup "safe hold" status in which they will need no external support but may be able to operate in only a limited way.

Thus, each spacecraft will exercise its own control, navigation and health monitoring with only occasional outside analysis of telemetry and delivery of system commands as supplements.

By the turn of the century life support systems will be closed and depend minimally on resupply from Earth. Intensive space agriculture will supply half or more of the crews' food, but animal husbandry will have to await further development. Fully recycling both breathing oxygen and water will reduce stores of makeup water to near zero and oxygen to negligible quantities.

Artificial gravity for space habitats will restore a more "normal" psychological environment for space workers and (perhaps) their families in long residence.

The natural radiation at high orbits will remain an impediment to extended extravehicular operation. Space suits with metallic foil shielding will be used for unscheduled tasks demanding EVA, but men will ride in protected small space vehicles with advanced manipulator devices to do the bulk of construction and other tasks outside the pressurized habitats and large transport vehicles.

Space suits will reject metabolic heat by radiation rather than by evaporating water. Advanced CO_2 regeneration will extend the allowable EVA duration to that of a long workday.

Routine servicing and resupply in the 1990s will support sustained operations, including a space center, in LEO and sorties to GEO. Servicing will be done by both manned and teleoperator vehicles.

Most servicing and repair will be done by removing expended or faulty equipment modules and replacing them. Limited repairs will be performed on the spot by man, but most repair will be done by taking the equipment back to the shop—a fully staffed space base—or will be done after return to Earth. Only very large refurbishment operations will require return of a satellite to Earth, since "full service" space bases will be in orbit.

Shuttle-type tankers will perform the majority of fluid resupply in space. They will either refill vehicles directly or deliver to space bases that will act as filling stations. Fluids will either come from Earth or be manufactured from Moon or other materials found in space.

From this picture of the technology base that will probably be developed in the '80s and '90s, we can project what will happen after the turn of the century. Missions from 2000-2020 will fall into the categories of commercial, scientific, exploratory, or military. The commercialization of space may span the gamut from communications platforms to proto-colonies in space, and include Earth sensing, manufacturing and materials processing, nuclear waste disposal, and lunar and asteroid exploration and mining.

The technological revolution of the past forty years set off by the invention of the transistor and other modern solid state devices is not expected to be repeated in the next forty years. The development of faster, denser, lower-power electronic devices will allow considerable improvement in communications systems without any new major inventions. With this assumption, it is possible to predict the state of commercial communications in 2000-2020.

By 2000, the present operational frequency spectrum will be unable to handle communications and remote sensing demands. In particular, the upward link of 6 GHz and down link of 4 GHz (C band) will be saturated in the late 1980s. The 12 GHz up and 10 GHz down (k_u band) will be saturated in the late 1990s. Even with the expected new technologies for frequency reuse, such as polarization and TDMA, these lower frequency spectrums will be unable to carry the traffic.

The overall demand for telecommunication services will grow by about a factor of five, and that carried by satellites will increase by at least a factor of ten. To alleviate the inevitable telecommunica-

tions log jam, another frequency band will be added—either 30/20 GHz or 45/40 GHz.

These bands will have the wide-band capacity for transmitting video at the same time they carry voice and data.

Early in the next century, holding teleconferences among participants on opposite sides of this country and throughout the world will be commonplace. Mail, newspapers, magazines, and other publications will be available directly in homes using dataphone and fax techniques. Most homes in developed countries and communities in developing countries will be able to receive broadcasts directly from satellites, and quite a number of government agencies and industrial organizations world wide will be able to communicate directly with satellites. Despite these new services, voice service will continue to account for a major portion of the demand.

The following communications satellite advanced technologies are expected to be operational in 2000:

- Multi-beam scanning antennas. They will allow a single satellite to service many different areas with many different transmissions.
- On-board switching and processing.
- High-power, all-solid-state systems.
- Low-noise, high-frequency-band transmitters and receivers.
- Inexpensive high frequency Earth terminals.
- High frequency components to support communications satellites, such as GaAs FETs for low-noise receivers and power amplifiers.

As an example of the communications systems that will have a major impact, F-8 describes a personal communications wrist radio system that will probably be in operation in the early years of the next century.

Remote sensing of the Earth from orbit will grow to span a portion of the electromagnetic spectrum having wavelengths differing by more than six orders of magnitude (0.3 μm to ~100 cm and possibly beyond). Powerful active sensors will be added to the arsenal. Most data will be selectively and automatically processed in space and relayed among special orbital centers for distribution to scientific, government, and business users.

The environmental satellite system of the future will combine manned and unmanned orbiters carrying advanced remote sensors that interact with remote sensors on land, in the ocean, and the atmosphere. What is sensed by one sensor will control the actions of other sensors. In this way the maximum amount of environmental information will be gathered through the minimum amount of collected data. Unmanned environmental spacecraft will operate at both geosynchronous orbit and highly elliptical, 12-hr, high-inclination orbits.

Constant improvements in sensors, data handling, and interpretation during the next twenty years will lead to routine acquisition and use of diverse resources data. Resource sensing will then

F-8 WRIST RADIO COMMUNICATIONS SCHEME

PURPOSE
To allow citizens to communicate through exchanges by voice, from anywhere

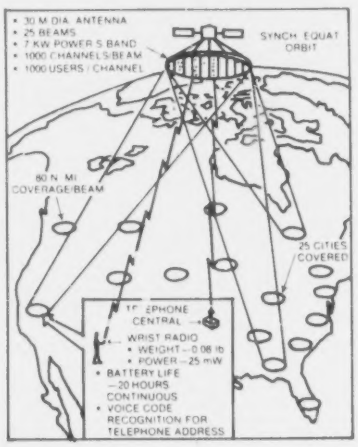
RATIONALE
Mobile telephones are desirable, but should be wrist worn. Many mobile users want communications

CONCEPT DESCRIPTION
Multichannel repeater and wrist transmitter-receivers connect people anywhere. Voice code recognition address (phone number)

CHARACTERISTICS
- Weight—4170 kg
- Size—30 m diam antenna
- Rad power—21 kW$_e$
- Orbit—Synch Equat
- Constellation size—1
- Life/servicing period—10/3 years
- Time frame—1990
- IOC cost—320 M$

PERFORMANCE
1 000 000 people in each of 25 cities can communicate. 25 000 simultaneously using normal voice

BUILDING BLOCK REQUIREMENTS
- Transportation—Shuttle and tug
- On orbit operations—automated or manual servicing unit
- Subsystems—attitude controls, antenna, processor
- Technology—large multibeam antenna, multi-channel transporter, LSI processor, multi-access techniques
- Other—wrist transceiver, LSI technology



be directed toward refined synoptic exploration of the planets, their moons, and other bodies, especially the asteroids.

Basic and applied research conducted in the late 1980s and 1990s will demonstrate that materials for commercial exploitation can be produced in space. We cannot say what the products will be or exactly how they will be made.

From among materials on which space research is being done, those that look as though they could be commercially exploited at the turn of the century include pharmaceuticals, infrared detector crystals, LSI circuit substrate, inertial configuration fusion targets, laser optics glass, large-particle monodisperse latexes, aligned magnets and ferromagnetic materials.

As an adjunct to terrestrial nuclear waste disposal, the removal by spacecraft of certain long-lived radio nuclides from the vicinity of the Earth has been studied since 1972. Too much nuclear waste is produced to dispose of it all in space with foreseeable available space transportation. However, removing from Earth the long-lived hazardous wastes such as the actinides, plutonium-240, americium-241, technetium-99, and iodine-129 would eliminate the long-term hazard. AIAA proposed a scheme in a January 14, 1981, position paper, "Nuclear Waste Disposal in Space."

The scope of lunar exploitation during the early 21st Century will depend upon making progress in using cislunar space and exploring with unmanned lunar missions during the 1990s. Even now, we know the Moon can be a substantial source of oxygen and structural materials for use in space. However, discovery of significant concentrations of high value minerals or frozen gases and liquids—especially water beneath the surface or in perpetually shadowed polar regions—would make exploitation more likely. Readily available water would make establishing self-sustaining colonies much easier and reduce transportation costs by supplying the raw materials for hydrogen and oxygen propellants.

Even if the industrial possibilities of the Moon are not realized, research facilities will probably be placed there. Near the lunar poles there exist constantly dark regions well suited to low temperature experiments. The lunar far side is an outstanding location for a major radio astronomy observatory.

At least some limited lunar research facilities seem likely to exist by 2000. Extensive manned lu-

nar missions would make significant propulsion demands. However, such missions would establish permanent manned facilities perhaps approaching the scope of colonies. These facilities would carry out applied lunar research, possibly manufacture propellants, and produce structural materials or other goods for use on the Moon or in space.

An asteroid landing may be conducted around 2000, and an unmanned sample return mission, about ten years later. Substantial asteroid exploitation will not occur before 2020. Asteroid missions could be carried out much sooner if early missions show an economic payoff big enough to rally support.

Post-Spacelab experimental free-flying manned platforms and facilities like the Space Operations Center (SOC) for a range of applications, including development of materials processing techniques in the 1990s, will pave the way for permanent habitats or "proto-colonies" in low Earth orbit around the turn of the century. These proto-colonies would house several hundred people under benign living conditions, including simulated gravity by rotation, and partially closed air, water, and waste systems. The residents would carry out a wide variety of physical and biological scientific investigations, space technology development, and manufacturing. Such proto-colonies may be international undertakings. Later they may lead to manufacturing plants and permanent habitats in geosynchronous and other orbits.

Basic physics experiments in space in 2000-2020 will extend the volume and duration of those conducted in the last two decades of this century. Fluid dynamics and plasma physics experiments will be conducted on large scales of space and time. Man-made problems, natural ground disturbances, and a baseline limited to the Earth's diameter have prevented detecting gravitational waves. The short baseline restricts the observable wavelengths to extremely short-period accelerations of very great masses, such as those produced by supernova explosions. A network of gravity wave detectors in GEO or at Earth-Moon Lagrangian points may detect waves from such sources as pulsars and binary systems of two neutron stars.

In optical astronomy apertures larger than 3-4 m will be needed to surpass the Large Space Telescope projected for the 1990s. Larger apertures would gather even fainter light.

In radio astronomy, space operation offers the opportunity to observe frequencies below the ionospheric cutoff (about 5 MHz), to resolve small structures with interferometers with very long baselines, and to avoid man-made and natural terrestrial background. An interferometric network will likely be established with several receivers in GEO between 2000 and 2005. The baseline may be extended to the Moon by 2010. A manned or man-tended observatory on the lunar far side, established about 2015, will completely avoid terrestrial background.

If we assume low activity in planetary exploration in the next 20 years, then by the turn of the century we will still not have flown complex orbiters around the outer planets, sent landers and rovers to their

moons, returned samples from Mars and other planets, or performed many other demanding missions. Assuming that the goals of scientific exploration of the solar system do not change substantially, these missions would still be planned. However, development of extremely capable in-situ instruments could reduce the advantages of sample return over a surface rover. Advances in robotics would make a surface rover even more attractive. Such a change would affect the need for advanced propulsion. A manned Mars mission would strain propulsion technology in the early years of the next century. Judicious use of aerodynamic braking at Mars, and manufacturing propellant from water at the polar caps or in subsurface deposits would substantially ease the propulsion needed. Nuclear propulsion will probably be used for advanced missions, unmanned or manned, late in 2000-2020.

Most outer planet flybys fall in the category of galactic probes, since they reach solar system escape velocity. However, their velocities will be too low and communications too limited to satisfactorily carry out a true galactic mission. A worthwhile extra-solar system probe would require a velocity well beyond those to which we have become accustomed. Of the candidate propulsion systems in 2000-2020, only nuclear electric has any possibility of application and, even so, will have to perform substantially better than it would for planetary missions if such missions are to be accomplished in a reasonable time—less than 30-50 years.

If the technology for creating super-efficient solar sails in space can be mastered and a vehicle carried by such a sail brought to a starting point near the Sun, very substantial velocities are possible. Nuclear fusion propulsion may also have potential. Certainly, there will be a substantial interest in extending our frontiers beyond the present solar system in the early 21st Century.

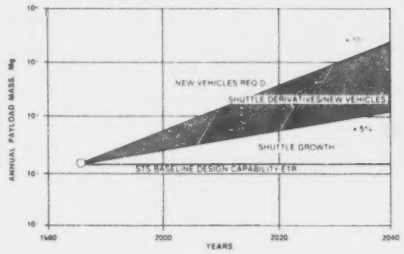
As space systems prove themselves during peacetime, and crises and survivability issues are resolved, many more military functions will be performed from space. Manned facilities will create new opportunities for military space operations.

Military systems will be called upon to defend civilian satellites as more high-value operations are conducted in space, and may well be integrated into some commercial and/or government systems for economy and protection. However, most military systems will continue to be dedicated.

Space-based weaponry may contribute to global stability, although in accordance with international agreements, orbital weapons of mass destruction will probably not be developed.

Typical military systems may include an integrated, survivable military communications network (F-9) giving a flexible, robust military command, control, and communications system and a highly survivable navigation system (F-10) for secure, reliable global positioning.

F-11 ANNUAL PAYLOAD TO LOW EARTH ORBIT
STS baseline: 30 Mg/flight, 50 flights/yr.

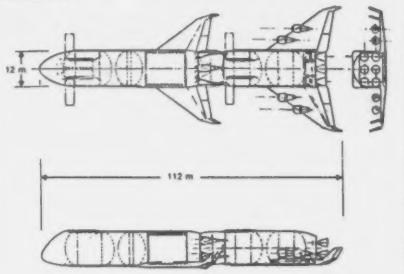


Separate military launch systems would permit more flexible scheduling than if all military missions relied on civilian launchers.

The missions described previously will depend not only on specific technologies and development of the required spacecraft, but also on large-scale support from transport vehicles, ground and orbital operations control facilities, and space construction bases.

The first step into space from the Earth's surface to LEO receives most attention today. Planners are increasingly realizing that the subsequent steps to higher energy orbits will require a new Orbiter-compatible OTV that is better and more economically matched to the missions of the late 1980s and early 1990s than the present IUS and other smaller stages, modules, and kick motors. Thought will have to be given to vehicles and propulsion stages for cislunar space, and for heliocentric and, later, galactic flight early in the 21st Century.

F-12 ADVANCED SMALL REUSABLE TWO-STAGE SERIES-BURN HLLV



After the Shuttle makes its early flights, its performance will be slowly raised by reducing mass and improving the main engine performance by increasing effective jet velocity. Turn-around time and operational costs will drop while useful life will increase. The thermal protection system, External Tank (ET), and Solid Rocket Boosters (SRB) will be improved. In the late 1980s or early 1990s a parallel burn Liquid Boost Module will probably be added to the aft end of the ET.

In the late 1990s a Liquid Propellant Rocket Recoverable Booster will replace the SRB both to improve payload and reduce cost.

Around 2000, traffic to LEO may have increased sufficiently to justify a completely reusable space transportation system. This system will operate like a commercial airline, carrying personnel and cargo into LEO at reduced cost. Early in the 21st Century the Orbiter will be able to transport relatively large numbers of persons into orbit for work or play with a passenger module in the cargo bay.

All these changes will increase the payload of the Shuttle 5% per year above baseline (F-11). When demand starts rising faster than 5%, new manned and unmanned vehicles will be built.

A derivative unmanned heavy-lift launch vehicle will carry more massive and larger cargos than the present Shuttle payload bay accommodates. An expendable shroud will cover the cargo during its rise through the atmosphere. After burnout the SSME will return to Earth in a recoverable module.

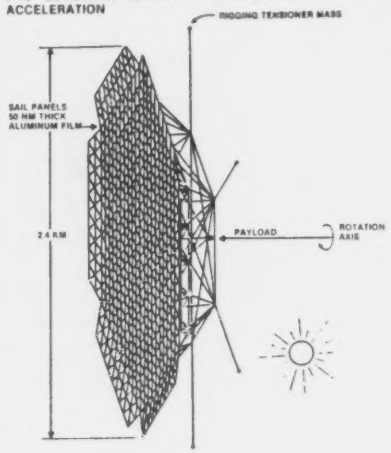
An advanced heavy-lift launch vehicle (HLLV) will be completely reusable and will lift four times the payload of the present Shuttle (F-12). The version in F-12 is a recent control-configured vehicle design. Its two series-burn stages give a large reentry cross range so that it can service many key orbital altitudes and inclinations.

A vertical takeoff single-stage-to-orbit vehicle will have an insulated structure, aluminum load-bearing tanks, and one dual-fuel and three oxygen/kerosene engines. It will have a mass of 1140 Mg at liftoff, 83 Mg dry, a payload capacity of 29.5 Mg into a 185-km eastward orbit from ETR, and a payload bay measuring 4.6 × 18.3 m.

An even more advanced horizontal takeoff, single-stage-to-orbit vehicle will incorporate multicycle airbreathing engines and a metallic, multi-wall thermal protection system. Besides transporting people and cargo to LEO, it could carry out space sorties, rescues, and other special flights or stay in the atmosphere as a hypersonic military and civil transport.

When traffic into LEO has increased sufficiently and requires frequent trips, a ground based

F-13 ULTRATHIN METAL-FILM SOLAR SAIL WITH 10^{-4} G ACCELERATION



multigigawatt laser system may be used to heat a propellant to high effective jet velocities for efficient and economic transport. Or, electrically driven rail guns or mass drivers may be used to launch heavy payloads to LEO.

Tethers extended from space stations for hundreds of kilometers may transport items to LEO and between LEO and GEO.

As geocentric space operations develop in the early 1990s, new orbital transfer vehicles for flights between LEO and GEO will most likely use modified RL-10 engines. Smaller high performance stages will also be built for transfer between orbits.

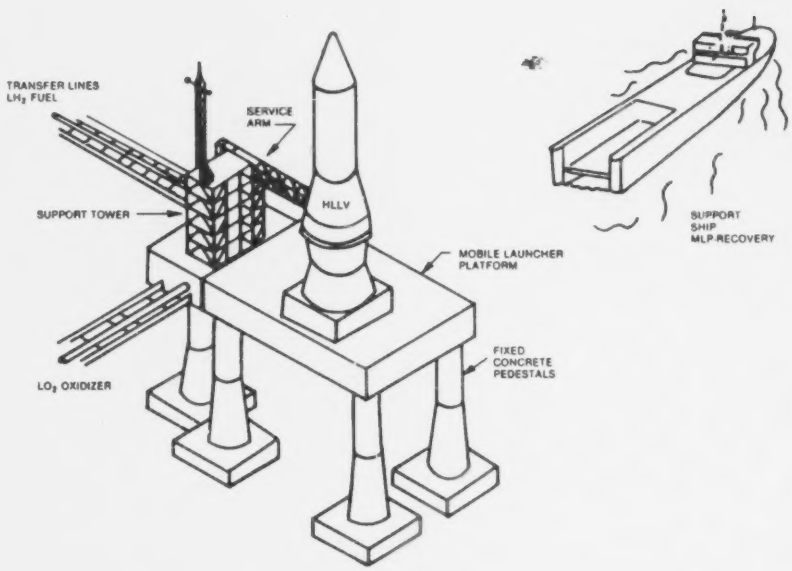
Though chemical rocket OTVs could, and probably will, be used for missions in cislunar space, a number of studies have shown that nuclear- or solar-electric powered OTVs could be comparatively flexible, effective, and economic.

Chemical rockets can continue to launch solar system explorers to the end of this century and beyond. Solar electric rocket stages will be used on a number of heliocentric missions before the end of the century and for most inner solar system missions in the 21st Century.

Nuclear electric rockets will be the workhorses of solar system exploration in the first 20 years of the next century. But much analysis and technology development is needed in the next twenty years to ready subsystems.

Depending on individual mission models, solar sails may propel heliocentric and extrasolar system

F-14 HEAVY LIFT LAUNCH VEHICLE OFF-SHORE LAUNCH SITE



craft in 2000-2020 and beyond. By exposing a very large area of extremely thin metal film to the solar wind the sail shown in F-13 would produce a respectable 10^{-4} *g* thrust with no expenditure of reaction mass.

As STS traffic develops in the late 1980s, emphasis will shift to improving effectiveness and economy of operations to insure routine, safe, and highly reliable performance of missions in the late 1990s. By the turn of the century, traffic into and in orbit will require highly sophisticated facilities and operational techniques.

An offshore launch site will probably be needed after the turn of the century. It may be at Cape Canaveral or near the equator. Experience and studies yet to be performed will determine the site. Frequent flights of HLLV would call for an offshore launch platform of the sort shown in F-14.

OTVs will be based at SOC or similar space platform. A SOC will be in operation by the mid-1990s or 2000 at the latest, and an attached OTV hangar will protect these vehicles from space debris and accommodate service and maintenance.

Equipment and techniques will be developed for extended extravehicular activity by astronauts, robots, and teleoperators—restrained and free flying. The robot's versatility in assembly and construction will save considerable payload mass because the same machine can perform a variety of operations. A computer in the robot exerting real-time control will handle many operations more reliably and effectively than a man guiding movements remotely.

Large structures in space at first will be fabricated on Earth and unfolded in space, then assembled in space, and still later partially fabricated as well as assembled in space.

Fabrication will become almost entirely, and assembly, considerably automated. Space construction personnel will use the same skills throughout the transition, but the skills will have a different focus. Man will continue to monitor the process and handle with machinery the subassemblies, but he will spend much more time maintaining the facil-

ity. The greater the automation, the greater the complexity of the structure.

Antennas will, for the most part, be ground fabricated and unfolded in space. This will hold for all types of antennas, reflectors, space-fed phased arrays, or hybrids. They will have powered mechanical joints and structural members and tension stays of composites to minimize thermal distortion.

A limited number of medium-sized antennas, with very exacting surface tolerances will be built on the ground. These antennas will pay for their superior figure with high weight and will usually need to be assembled in their operating orbits.

Platforms will be built in all three ways but only the very largest will warrant space fabrication. A typical platform in the year 2000 will have an area of about 1000 m^2 with structural members mostly 5-15 m long. By 2020, some platforms will have grown to 10,000 m^2.

Manned facilities will be well established by 2000. They will be able to carry out construction in 2000 and will house early space factories by 2020. The factories will process raw materials into usable materials for construction of advanced communication satellites, observation platforms, defense systems, and interplanetary vehicles.

Around the turn of the century some large space structures will still be deployed from the Shuttle payload bay or assembled and tested while attached to the orbiter or in adjacent space.

In 1990-2000, the only construction base will be in LEO (T-6). This platform will be an upgraded 25-kw_e power module with a workbench 30 m long. A crew will man it only when the Shuttle Orbiter is docked to it.

By 2010-2020, SOC or other space stations will have taken over as the LEO construction base. The stations will be bigger than the power module building block, have a simple cargo and machinery handling system, beam builders for economical in-orbit fabrication and assembly of space structures, and moderate power and will serve as a space depot. Its crew will remain on board between Orbiter visits. By 2000-2010, a line shack in GEO will perform the same functions as the earlier LEO power module.

Large space platforms will need only modest support facilities on Earth. Neither reprocessing materials for space fabrication nor fabricating building block structures on the ground will demand unusual new plants, with one possible exception. Some structures designed for ground fabrication and space unfolding need ground rigging and verification of the unfolding. This check means carrying out at 1 *g* a maneuver designed for zero *g*. Doing so presents a technical challenge and seems to demand buildings and simulation equipment bigger than the article to be unfolded.

In an extrapolation of technology covering 40 years, present events have enormous influence. Thus the review of space policy being carried out under George Keyworth's Office of Science and Technology Policy will greatly affect the accuracy of our conclusions. The space policy will probably emerge some time after the National Security Council makes its recommendations this summer. Judging from the administration's past tendency to stick with present space systems, which could be changed by international events, we judge the "guesstimates" in this article may be optimistic.

T-6 SPACE CONSTRUCTION BASES

	2000		2020		SPS	
Characteristic	LEO	GEO	LEO	GEO	LEO	GEO

SPACE

We will return to the Moon for private and government space developments, but lack the laws and international agreements to prevent conflict in such major space activities

by George Mueller
System Development Corp.

The 21st century in space

Speculating on our future in space has been a pleasant diversion for space scientists and popular writers. Although most predictions have not proved accurate, no one really much cared.

Today, however, we have good reasons *to care* about what will occur in space in the next 25 years. I refer not only to the military threat, but to economic, political, and legal ramifications as well. Since space development appears to be accelerating, important actions should be started now that will permit the world's political and legal structures to cope with a "brave new solar system."

Technology not the determinant

A modern-day Nostradamus must be much more accurate than in the past. Unfortunately, our predictive tools today are not much better than they were in the 16th Century. To one degree or another, we have always been able to predict what *could* happen; the problem has always been to predict what *will* happen.

Consider our situation. We have the technology to support any reasonable space activity we can imagine for at least the balance of this century. We can—and will—accomplish many exciting and far-reaching space developments in the next two decades without the need for further technological breakthroughs.

Unfortunately for the predicter, *political* and *economic* factors will determine the course of events far more than will technological developments. Because of the vagaries of these essentially human factors, moreover, the prophet can only forecast trends that pass some test of reasonableness.

George Mueller directed the NASA Office of Manned Space Flight at the height of the Apollo program and led Shuttle and post-Apollo planning. He was subsequently president and chairman of the board of System Development Corp., president of the AIAA, and is currently president of the International Academy of Astronautics.

Fortunately, however, it is possible to describe some of the space activities we can expect to see by the turn of the century in terms of trends rather than specific timetables. These activities have the potential of greatly expanding both the physical resources and the knowledge of mankind, but they likewise will raise new and knotty legal issues that we have not had to face before.

First, and regrettably foremost, terribly effective weaponry could well be deployed in space by the year 2000, weaponry that can attack both satellites and space stations as well as targets here on Earth. Our goal must be to ease world tensions so that this weaponry will not be deployed. Otherwise, every accomplishment I forecast in this article will be in jeopardy. On the assumption that the world powers *will* draw back from military confrontation, I can confidently predict widespread space activities by the year 2000. We are already seeing an acceleration in the number of space projects being planned and carried out.

In 1980, for the President's Office of Science and Technology Policy, AIAA projected the non-federal demand for space transportation through the year 2000. It concluded that this demand would increase from the 1980 level of one equivalent full-orbiter payload to 25 such payloads annually by the turn of the century. This report was greeted at first with considerable skepticism. After all, since the projection assumed the advertised Shuttle payload capacity, and since it excluded military and other government missions, it implied a load on our Space Transportation System far beyond that

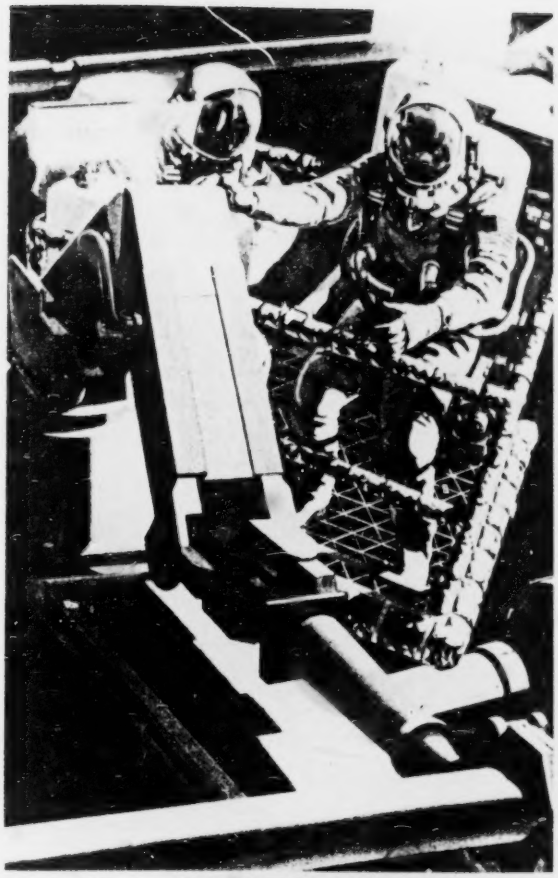
Copyright © 1984 by the American Institute of Aeronautics and Astronautics

programmed for the Shuttle. Now the skepticism has all but disappeared. The high-traffic forecast of the Battelle Outside Users Payload Model (see graph) tracks the AIAA projections very closely for the next 10 years. (I have not included Battelle's longer-term forecasts because they use a "bottom-up" model which does not cover 1990-era programs not defined today.)

Many of the projected payloads add to our growing satellite communications capability. Indeed, experts expect the demand for communications to double in just the next four years. With present techniques, this demand would completely saturate the geostationary arc by the year 2000. We will be seeing new techniques employed to increase bandwidth and communications efficiency; some of these techniques have already begun to be deployed in recently launched satellites. Probably there will be larger communications platforms with time-shared multibeam antennas.

Global newspapers

Communication capacity has already surfaced as a legal issue. The World Administrative Radio Conference held in 1979 resolved to hold conferences in 1985 and 1987 to guarantee countries equitable access to the geostationary satellite orbit. Assuming the intertwining technical and legal issues will be resolved, by the year 2000 satellite communications will be beamed to any place on the globe at extremely low cost. Direct-broadcast newspapers created in this period will have an enormous impact in overcoming international and social barriers. By the same token, worldwide news distribution will grant broadcasters vast propaganda potential, and I see no practical way to impose a requirement for responsible, factual reporting. Newspapers with audiences of a few hundred thousand have not been able to achieve completely objective reporting—and tomorrow's audiences may number in the billions. This global audience will have to sort out the truth from reports of different broadcasters with differing viewpoints, but at least they will have access to differing viewpoints. Competitive reporting provides increased understanding and knowledge throughout the world.

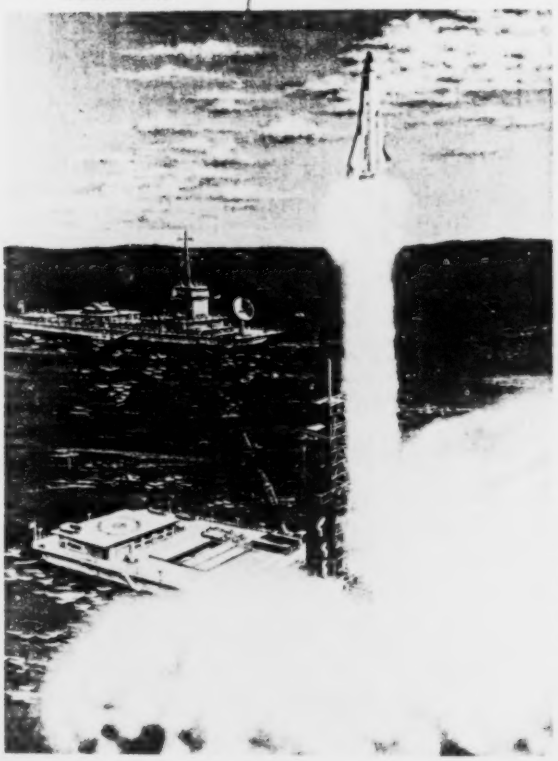


Efficient symbiosis of machines and people is essential to the development and assembly of large space structures and to the in-orbit servicing of scientific spacecraft, large multipurpose communications satellites, and space-based factories.

Newspaper broadcasts are by no means the only vehicles by which satellite communications can increase knowledge. By the year 2000 computers will provide access to the text of all the books and periodicals written since 1950. With a simple viewing device anyone will be able to acquire the knowledge contained in the libraries of the world (and, incidentally, play havoc with today's copyright laws). The impact of this development will rival the invention of the printing press.

On a less lofty plane, this same communications capability will dramatically alter the advertising and distribution of consumer goods. Suppliers will be able to advertise their products to billions of customers. We may well see a global interactive mail-order system. With that development, today's system of tariffs and protected industries will become obsolete.

A fully reusable single-stage-to-orbit dual-fuel shuttle lifts off from a barge. Such concepts tempt planners with their promise of lower mass-in-orbit and operational costs. Shuttle shows aerodynamic shape developed by NASA Langley Research Center. Illustration courtesy of System Development Corp.



I fully expect that the pressures of our dwindling terrestrial energy supply, as well as the serious climatological impact of increasing levels of combustion-generated atmospheric carbon dioxide identified recently by the Environmental Protection Agency and the National Academy of Sciences, will move us to derive energy from extraterrestrial sources (most probably solar power) collected outside the atmosphere, used in space, and beamed back to Earth.

The feasibility of a solar-power satellite has been much studied. Because of technical risks and costs, I do not believe it likely that a solar-power satellite will be built, at least in this century, but the prospects for a *lunar*-based solar power station are much brighter. As suggested by David Criswell, of the California Space Institute, it could be largely constructed using materials mined and processed from the Moon and asteroids. More than 90% of a solar power station can be created in situ without the great expense of transporting hundreds of thousands of tons of materials from Earth. Without significant additional technological developments, a pilot solar generating facility could be operating on the Moon in about ten years. By the early years of the next century, commercial-scale lunar-based solar power plants could be supplying a significant portion of the Earth's energy.

Moon power

The economics of the project are so attractive that it may well be the first of the lunar-based commercial projects. The UN should not delay in establishing an acceptable system of defining territorial rights on the Moon. If the lunar solar project is developed—and subsequently owned—by one nation, that nation would have a great advantage in lunar development. The lunar materials-processing plant surely would not be restricted just to building solar panels for long. Without some territorial apportionment, the first nations to begin developing the Moon would effectively own the Moon.

Presumably, the generated power would be sold to customers in any nation on a free-market basis. But the nations operating the facility might well elect to do otherwise. As terrestrial energy resources dwindle further in the 21st Century, the lunar source of power could be granted, or withheld, or differentially priced, based on national political or economic considerations. Such an approach

is not without precedent here on Earth. Such an act—or the threat of such an act—would certainly strain international relations and could restrict the potential of the project as a human resource.

One approach would be to have international ownership of the Moon and its resources. The nation or organization that develops each project might be given a lease, much as oil companies are granted leases to develop government-owned land. In return they would be required to sell the energy on an unrestricted basis at a fair market price. The problem lies in obtaining adequate return on the tremendous front-end investment required for such a project.

Space factories

This is not the only way to establish a system of territorial rights on the Moon. It may not even be the best. The point is that lunar development almost certainly will commence before 2010, and some acceptable system must be devised to avoid a clash of competing nations.

Further, we should not assume that space development will always be by national governments. By the year 2000 the private sector will have emerged as a factor in space industrialization, just as it has in satellite communications. Although projects of the magnitude of a lunar solar power system will undoubtedly be government-financed for the foreseeable future, many space factories may not be.

With the Space Shuttle flights of the next few years, many experiments will be conducted to determine the feasibility of space manufacture or processing. A sizable percentage of these experiments, I predict, will lead private corporations to invest in materials processing or other manufacturing in space.

We have already seen a highly successful materials-processing experiment designed by Johnson & Johnson and McDonnell Douglas using continuous flow electrophoresis (a process not very efficient on Earth) to produce urokinase, the pharmaceutical so effective in dissolving blood clots. McDonnell Douglas projects commercial operations beginning as early as 1986.

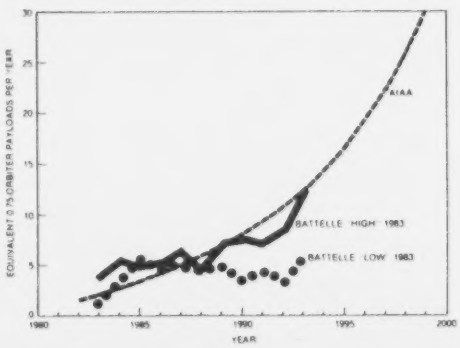
The concept of materials processing in space is certainly gaining acceptance. The 1983 Battelle study projects as many as 121 such payloads in orbit by 1997, 15 times more than the AIAA projected in its 1980 study.

Since both NASA and DOD appear to be phasing out launches of expendable vehicles such as Thor, Delta and Atlas Centaur, while allowing private operators to continue such launches, the only major government-operated space transporters will be the Shuttle and the Ariane. I doubt these two systems can meet the demand that is growing so rapidly.

This situation appears to call for the development of a second-generation Shuttle. Designed to be a fully reusable single-stage-to-orbit system, as suggested by Robert Salkeld of System Development Corp., a second-generation Shuttle would cut launch costs sharply—so sharply, in fact, that it would undoubtedly increase the demand, since far more projects would become economically attractive.

NASA has not shown strong support for a second-generation Shuttle. I believe that the private sector will invest in its own space transportation system. A number of firms are already seriously investigating the matter. Unencumbered by a bureaucracy, an expensive infrastructure, and a maze of regulations, private industry could operate a space transportation system much like an airline. With low launch costs, private industry could compete quite favorably with the Shuttle and Ariane. For this reason alone, I fully expect at least one private reusable space transportation system to be operating well before the end of the century.

To make such an operation feasible, space launches will be very different than they are today. I envision onboard checkout, minimum ground maintenance, and erector-type launch facilities (see illustration), and possibly manned vehicles



AIAA projections, supported by three Battelle Institute analyses, describe accelerating space development that will severely strain space transportation system capacity by the 1990s. As presented in *Astronautics & Aeronautics* in March 1981, this graph gave launch-demand projections for all non-federal payloads to be delivered by U.S. vehicles. It assumes a third of the foreign market will be captured by the U.S. AIAA made its assessment for the President's Office of Science and Technology Policy.

launched from barges—in international waters to avoid the most onerous of government controls.

These can hardly be considered radical concepts. Mobile erectors were used for V-2 launches 40 years ago. The Germans could roll a 46-ft V-2 into a field in Holland, fuel it, erect it, and launch it—all in 45 minutes. In the early '60s, erectors were used on the Atlas program to launch the 90-ft missiles; the legendary "Hollywood Hard" emplacements were designed to permit fueling, erection, and launch in only 20 minutes.

With proper forethought, the launch

---

of the second-generation Shuttle will be far simpler than that of an Atlas, and certainly will be far less complex than the current Shuttle demands, for it will invoive servicing only a single completely reusable vehicle.

For such reasons I foresee private corporations operating routinely in space. In addition to undertaking transportation, materials processing, and other space manufacturing, private companies or consortia will, I believe, mount projects to recover extraterrestrial resources, most likely by mining asteroids. Since many asteroids are rich in platinum-group metals, which have a value now of more than $20,000 per pound, the return-on-investment potential from an asteroid-mining mission is sure to interest commercial companies.

As the private sector relieves NASA more and more of space development operations, the agency will be able to return to its originally intended role. I envision scientific missions, in particular planetary exploration, increasing sharply from the current low. Today's budget of around $200 million severely hampers this important part of our space program. Despite the spectacular success of Viking, Mariner, and Voyager, Galileo is the only major interplanetary exploration program now approved.

The program outlined last April by NASA's Solar System Exploration Committee (SSEC) seems well thought out. It encompasses three initial missions: a Mars geoscience and climatology orbiter, a Titan probe and radar mapper, and a comet rendezvous and asteroid flyby. All would be launched in the 1990 era, and would be followed by missions such as a Mars surface probe, a Venus atmospheric probe, Saturn and Uranus flybys and probes, and a Saturn orbiter.

These missions, it seems to me, have an excellent chance of gaining approval and funding. Only one completely new spacecraft, the Mariner Mark II, would be required under the initial SSEC proposals, since the Mark II's modular design would be reconfigurable for other probes. Particularly if missions are conducted by international collaboration, I anticipate much solar-system exploration before the turn of the century.

The discovery that perhaps could change most the course of space exploration and even the future of mankind would be success in the search for extraterrestrial intelligence. Contacting other intelligent life would completely change our provincial world perspective of man's role in the universe.

Even if contacts elude us, space will undoubtedly stimulate many other projects in the next 25 years. With certainty I predict diversity and the unexpected. But we are not prepared in terms of laws and international agreements to deal effectively with what we *know* will come in space. Developing law to govern here on Earth took centuries. We have perhaps a decade to develop a comprehensive *and acceptable* body of law for space. We had better drop the postures of national competition that characterized our start in space and develop instead a spirit of international cooperation. Otherwise, we put at risk access to the incalculable resources of the universe.

CHAPTER THREE

HISTORY OF NASA AND ITS RELATIONSHIP TO UNITED STATES SPACE POLICY

By George N. Chatham
Specialist in Aeronautics and Space

I. INTRODUCTION

The purpose of this chapter is to sketch the origins of U.S. civilian involvement in aeronautics and space activities with particular reference to Government organizations of which the National Advisory Committee for Aeronautics (NACA) was the first, and of which the National Aeronautics and Space Administration (NASA) is now the largest and most important agency.

Short of a multi-volume effort, it is not possible to trace all aspects of this history and the policy issues which have surrounded the growth of the U.S. capability in space. The chapter puts into historical perspective the creation of NASA and treats selected policy issues which arose during its growth and evolution and how these were resolved. Unresolved issues remain, and Chapter Two has identified the principal ones of these issues.

II. FROM THE WRIGHT BROTHERS TO SPUTNIK

A. After the Wright Brothers Flight

The Wright brothers [1] succeeded in a controlled, straight line, powered flight on December 17, 1903. No one understood better than the Wrights how much they had yet to accomplish to evolve a maneuverable and stable vehicle from this first one capable of only a shallow, nearly ballistic flight.

Intensive work and flight trials continued over the next three years, mostly from an open pasture near Dayton, Ohio, and the point was reached where a maneuverable flying machine could be demonstrated. Although the belief was still strong in the United States as well as Europe that powered, manned flight was not possible except by buoyant flight, the Wrights had accumulated a number of eyewitnesses who knew that, despite the plentiful expert testimony to the contrary, man had indeed achieved powered flight. Among these eyewitnesses were a few wealthy Americans who were prepared to back the Wrights, and an even larger number of influential Europeans.

Incidental to their research, the Wrights had obtained for their designs and inventions patent coverage that would warm an in-

vestor's heart and bring despair to competitive designers and inventors. Objections to the Wright patent "blanket" were strenuous,[2] but to no avail. For example, the Wrights' system of lateral control was to warp the wings, a technique they never saw the need to abandon. According to the courts, other systems, e.g. the independent movable control surface of Curtiss, or the modern system of a deflectable panel on the outer trailing edge of the wing, were all covered by the Wrights' claims. Such was the power of the Wrights' legal position that, in those early days, no one in the United States could contemplate commercial construction of aircraft without making a financial arrangement with the Wrights. Air shows, the most lucrative and only practical civilian use for the airplane, routinely paid large sums to the Wrights in advance to curtail legal stop orders or successful law suits.

There can be no doubt that the Wrights' patent position and penchant for swift legal enforcement was a significant factor in retarding aeronautical development in the United States compared to Europe in the years just prior to World War I. However, it was not the only factor, or perhaps not even the most significant one.

During the period between 1906 and 1908, the Wrights began serious efforts to "sell" their airplanes. Their price of $25,000 (which included flying lessons) was today's equivalent of about $180,000.[3] The Wrights thus greatly simplified their marketing effort. It would be an item for the consideration of governments or perhaps the more daring of the world's extremely wealthy.

The United States, being the dominant power in the Americas and separated from Europe by a distance still considered vast, saw the airplane as a curiosity of dubious military value—but would witness a demonstration, scheduled August 28, 1908 at Fort Myer, Virginia, but only following a lengthy paperwork routine.

Aeronautical interest in Europe sharply contrasted with that in the United States in nearly every major aspect. Within a geographic area about equal to that of Texas, a tight cluster of traditionally competitive nations were in a temporary state of restless and vigilant peace. These governments were far more interested in the potential military utility of flight. Also, each nation contained its own group of wealthy industrialists and each nation contained another group not to be found in the United States, a wealthy nobility. Further, manned flight by means other than buoyant flight had been a subject of speculation and research for hundreds of years.

In the interest of tight schedules for promised demonstrations in the United States and in Europe (France), the Wrights decided to separate: Orville was to fly in the United States and Wilbur in Europe. The demonstrations at Fort Myer were successful in dispelling the long-standing suspicion of the press and much of the public that the Wright aircraft as well as the Wrights themselves were fictitious. The test requirements were interrupted by a crash which injured Orville and killed a military passenger, Lt. Thomas Selfridge.

Wilbur, in Europe, flew initially from Hunaudieres race track near Le Mans. His first flight was enough to crush the suspicion of the

[3] Calculated from Consumer Price Index Series which shows today's dollar has the buying power equal to $0.14 in 1910.

French press that he was a "bluffeur" [4] and to make him an instant hero. With his continued flights, his fame became international and his passengers included a rich sampling of Europeans including English nobility, high-ranking military and wealthy industrialists. Also in his audience were some of Europe's aspiring and experienced successful producers of new designs which were to evolve swiftly under the pressure of war into aircraft far in advance of that achieved by the Wrights.

As the winter of 1908 began to produce poor flying weather, Wilbur moved to Pau, a resort at the foot of the Pyrenees, where he was joined by the recuperating Orville and their sister, Katherine.

As their demonstrations continued through the spring of 1909, it seemed to the Wrights that, with the numerous agreements they had developed; with a French-Wright Company, a German-Wright Company and an Italian-Wright Company, along with their company in the United States, they could look forward to a bright future in which they and their now immortal "Wright Flyer" would dominate world aviation.

After a triumphant return to the United States in 1909, Orville successfully completed his military test and sold a few Wright Flyers to the Signal Corps and to the Navy. However, he found that the manufacture and sale of his aircraft was relatively small on potential income compared to that possible from air shows. For the purpose here it will suffice to say that following Wilbur's death, May 30, 1912, Orville continued a highly profitable air show career as he steadily refined his design of the Wright Flyer, but world aeronautics had already passed him by.

The state of the aeronautical art in both Europe and the United States was so swift that the Wrights' companies in Europe found themselves with no market. Production of all manner of aircraft boomed in Europe prior to World War I but remained almost dormant in the United States. "On the eve of World War I (1914), France was reported to have 1,400 airplanes, Germany 1,000, Russia 800, Great Britain 400 and the United States 23." [5]

B. The United States Adopts the British Approach

Federal action, or rather the lack of it, clearly showed that neither the United States military establishment nor Congress was disturbed by having been left by Europe in what amounted to a "technological backwash." [6] However, matters pertaining to aeronautics tended to appear complex to both the administration and to Congress. Dr. Charles D. Walcott, Langley's successor as Secretary of the Smithsonian Institution, along with other aeronautical enthusiasts, some from industry and some from the military, had pressed Congress and the administration for years to take aeronautics under the Federal wing as important to the Nation. Great Britain had established its own solution to determining a Federal role in aeronautics by establishing an Advisory Committee on Aeronautics in 1910. Walcott sought

the same type of body to advise the Federal Government and provide guidance to a national research laboratory.

Walcott and others advanced numerous plans between 1911 and 1915, saw them fail for one reason or another. However, the experience of accumulated failures gave Walcott increasingly sharp skills in the art of lobbying.[7]

He obtained the introduction of a joint resolution based on his earlier Smithsonian memoranda for the advisory committee and national laboratory. Franklin D. Roosevelt, then Assistant Secretary of the Navy and, for this resolution, spokesman for the administration. approved the resolution.

C. NACA is Formed in 1915

Senator Ben Tillman and Congressman Ernest H. Roberts introduced the joint resolution to establish NACA, but despite the favorable committee report and administration support, it appeared that adjournment, scheduled for March 4, 1915, would allow the resolution to die. Congressman Roberts suggested a familiar congressional maneuver to prevent this. There was sufficient time to tie the NACA enabling legislation to the Naval Appropriations Bill as a rider. In this form, the NACA bill was signed by President Wilson on March 3, 1915, with an appropriation of $5,000 for the first year of operation.

Twelve presidentially appointed non-paid members from the Government and the civil scientific community were "to supervise and direct the scientific study of the problems of flight, with a view of their practical solution," and to "direct and conduct research and experiments in aeronautics." All members, even of the later technical subcommittee, served without compensation except for travel expenses.

As a first act, the new National Advisory Committee set about to sum up the state of aeronautics in the United States. This was indeed a brief task. Orville Wright was still improving his Wright Flyer and conducting air shows, but it was clear that flight tecnology has passed him by years earlier. The "industry" consisted of a few handicraft shops, owned by enthusiasts who had either paid the Wright Company a license fee, were in litigation with them, or who had not yet tried to sell an airplane. There was interest and some activity in the military services, the Bureau of Standards and in the Weather Bureau, but coordination was nonexistent. The need for a national laboratory was clearly proven by this survey, emphatically confirming the views which had been advanced by most committee members for years.

However, few in Congress, nor anywhere else, knew of the existence of the Advisory Committee. In fact, during Senate hearings in 1918 on aircraft production, none of the committee were called to testify and one Member who had heard about the Committee spoke of it in the past tense.[8]

The Committee did publish a glossary in which the "aeroplane," for purposes of identification in the United States, became "airplane." The science behind the vehicle, however, remained "aeronautics."

Despite the nearly complete apathy of the Congress toward the goals of the Committee, they had made progress toward their labora-

[7] Levine, op. cit., p. 12.
[8] Kelly, op. cit., p. 49.

tory in incremental, informal steps. It was to be located at Langley Field, outside of Hampton, Virginia.

By the time the administration officially approved the transfer of the land to the NACA (President Wilson, April 24, 1919), the buildings and land preparation were largely completed. Then, formal dedication took place on June 11, 1920, and NACA had its national aeronautics laboratory, the Langley Memorial Aeronautical Laboratory (after Samuel P. Langley).

D. A Philosophy Emerges

An early concern, voiced by Roosevelt when he spoke for Wilson's administration to approve the concept for forming an advisory committee for aeronautics, was that civil interests might evolve to dominate the committee at the expense of Government (military) objectives. He recommended changes in membership which would retain a "controlling interest in the activities of this proposed committee." [9]

Still fresh in Roosevelt's memory was the shock of finding that the United States' own pioneers had demonstrated the first workable powered aircraft to Europe and now, only seven years later, he could claim only a spectator's seat in this international arena. In his endorsement of the Advisory Committee, cited above, Roosevelt observed that the European war tensions had brought on a "great military necessity" which had fostered a "rapid development of aircraft and demonstrated the practical utility of these vessels of the air, and has placed this country far behind in the use of aircraft." [10]

The committee, on the other hand, had always envisioned a far more elementary role. That there would be no effort to aid the military or the civil industry in a game of "catch-up," except as the revelation of fundamental principles, ". . . to increase the safety and effectiveness of aerial locomotion for the purposes of commerce, national defense, and the welfare of man." [11]

The Committee remained firm in their intended scope of effort, repeatedly assuring all that their efforts would be purely scientific and that all construction and operating activities would be "left to the Army and Navy and to individuals." [12]

Coupled to this resolve to remain academic was an equally powerful commitment that no researcher's work should be directed. Requests for research would be considered but assignments, regardless of origin, could not be made. This high degree of autonomy was a source of double irritation to the military. In the early days of the Langley laboratory, the NACA people became such an anathema to the military that a concerted effort was made to make them vacate the premises. In General Billy Mitchell's words: "It is difficult to handle this National Advisory Committee in any way. It (the NACA) does no good here nor any

other place that I can see and there is a project of law now for its abolishment which I hope will take place." [13]

NACA Senior Staff Engineer, L.M. Griffith, claimed that at a meeting of the Air Service Officers on June 15, 1920, the "possibility of ousting NACA from the field" was discussed and Col. Hensley "promised to do every thing within his power to bring this about." [14]

Nevertheless, the Langley laboratory survived and continued its efforts to correlate wind tunnel findings with full scale flight tests and to develop the needed tools for aerodynamic study—the nonexistent instrumentation and recording systems which would reveal the relative performance of aerodynamic surfaces as well as flight vehicles under varying flight conditions.

Then, in the mid-1930's the signs of war in Europe again appeared. Reports began to reflect rapid progress in all areas of aeronautics in Europe, primarily in Germany. NACA Chairman, Joseph S. Ames, reported to Congress that United States supremacy in available research facilities was "seriously threatened." [15]

NACA Director of Aeronautical Research, George W. Lewis, after an extensive tour of Germany and Russia in 1936, had found that any claim by the United States of supremacy in aeronautics was optimistic. Charles A. Lindbergh, members of NACA, also toured German aeronautical centers and industrial facilities. His correspondence with Ames was blunt and clearly warned that the United States military air capability was obsolete by German standards. He also confirmed the high productivity of the German industry but warned that new design development at a faster rate was needed, else "Germany continue to be the leading country in the world." [16]

A deep concern over the prospect of United States participation in a war with Germany swept through the military and also through the NACA. In 1936, the joint Army-Navy Aeronautical Board reached the conclusion that in the event of war, NACA should give up its independence and place itself under the direction of the Board. Shortly thereafter, a special NACA subcommittee was convened by Chairman Ames to consider this viewpoint.[17] Their decision was the same as that of the Board with the recommendation that, in a state of war, chairmanship of the NACA should be transferred to the chairman of the Army-Navy Aeronautical Board, General Oscar Westover, who was also Chief of the Army Air Corps.

Lewis visited Europe once again a few months before the outbreak of war in September 1939. His German hosts allowed almost complete freedom of travel. Lewis brought back yet another confirmation of the enormity of the German aeronautical progress, productive capacity, and readiness for war. This information was relayed to Congress by Vannevar Bush, who replaced Joseph S. Ames in 1939 on his retirement. Along with it, Bush made a successful plea to increase the personnel and facilities of the NACA.

A new aeronautics and wind tunnel facility, the Ames (after former Chairman, Joseph S. Ames) Aeronautical Laboratory, was authorized by Congress in 1939. It was located at Moffett Naval Airfield 40 miles south of San Francisco. Construction began on September 14, 1939, a few days following the authorization.

The new aeronautical facilities would be put to heavy use immediately, but they were not enough. Lindbergh had repeatedly warned that aircraft propulsion systems were as obsolete as the United States military aircraft. He urged that a new center, specializing in aircraft engine technology, be established immediately. In June 1940, Congress agreed. A site was made available at the Cleveland, Ohio municipal airport for this center, to be known as the Lewis Flight Propulsion Laboratory.

During the war years, 1941–1945, NACA efforts were almost totally in applied technology. New fighter aircraft began to appear and essential changes to increase their speed, indeed to make them reasonably safe to fly, placed a double and sometimes triple shift of work load on the NACA Centers

Following the war, the NACA returned to a more orderly routine but found an equally great, although quite different, challenge and responsibility. Its own bank of basic research, built up during the 1920's and early 1930's, had been exhausted in the early war years. With peace, the NACA had become heir to large quantities of more advanced German research, not only in aeronautics but also in propulsion and rocketry.

Integrating the German research and pursuing their own, which had been shelved during the war years, produced a decade of progress into flight regimes believed to be impossible by many aerodynacists in the 1930's. Rocket engines permitted the exploration of high-speed subsonic flight, transonic flight and supersonic flight. The rapid development of the jet engine permitted the practical application of this fresh bank of data to revolutionize military aircraft. At the same time, rocketry and the art of missile weaponry was evolving rapidly beyond that of the German V–2. Success with missile development was such that its advocates had begun to question whether or not the manned military aircraft really had a future role.

Von Braun made numerous comments to the effect that he saw the V–2 more as a precursor to a space ship than as a military weapon. Some of his points are made in a 1945 interview at Wright Field.[18] He noted that:

> The whole of the Earth's surface could be continuously observed from such a rocket (in Earth orbit). The crew could be equipped with very powerful telescopes and be able to observe even small objects, such as ships, icebergs, troop movements, construction work, etc. They could also carry out physical and astronomical research on problems which could only be tackled at that altitude, due to absence of the atmosphere.

E. Early Interest in Rocketry

Von Braun's enthusiasm and the large quantity of V–2s and other hardware transported to the United States from Peenemunde deeply

[18] Zwicky, Fritz, "Report on Certain Phases of War Research in Germany," U.S. Air Force, Air Material Command, Wright Field, Dayton, Ohio, 1947, 38–42.

impressed research teams in four military services. However, a conservative stance by their superior officers served to counter enthusiasms. Dr. Vannevar Bush. Director of the Office for Scientific Research and Development (OSRD) expressed disdain for the future of rocketry, even as a long range weapon. He testified before the Senate Committee on Atomic Energy in December, 1945: [19]

> There has been a great deal said about a 3.000 mile (4,828 km) high-angle rocket. In my opinion such a thing is impossible and will be impossible for many years. The people who have been writing these things that annoy me have been talking about a 3,000 mile (4,828 km) high-angle rocket shot from one continent to another carrying an atomic bomb, and so directed as to be a precise weapon which would land on a certain target such as this city. I say technically I don't think anybody in the world knows how to do such a thing and I feel confident it will not be done for a very long period of time to come. I think we can leave that out of our thinking. I wish the American public would leave that out of their thinking.

The OSRD was combined with the Joint New Weapons and Equipment Board (JNWEB) and became the Joint Research and Development Board (JRDB). However Vannevar Bush remained as Chairman of this new review board, the function of which was to "coordinate all research and development activities of joint interest to the War and Navy Departments, so that the War and Navy Departments will establish and carry out a strong, unified, integrated and complete research and development program in the field of national defense." [20]

His influence, or rather, the position of the Board at this time, was adequate to prevent any unification of interests or joint project for orbital developments between the various interested groups which could be found in the Army Ordnance Corps, the Navy Bureau of Aeronautics (Bu/Aer), the Naval Research Laboratory and the Army Air Forces.

1. The Army Ordnance Corps

This group was responsible for "Operation Paperclip," the rescue and salvage mission which resulted in the transfer of Wernher von Braun and other distinguished German scientists, along with their stock of V–2s and other hardware from Peenemunde to the United States in May 1945. From 1945 until 1949, the German team from Peenemunde and the Ordance Corps assembled, studied and launched the stock of V–2 rockets from White Sands, New Mexico carrying aloft a wide assortment of scientific payloads. Although the V–2 was the world's most technically advanced rocket during this time, it was certainly no space ship—only a short range ballistic missile. The early interest of the Ordance Corps in satellites had faded and in 1949, Dr. Von Braun and his group were moved from the Army Ordnance Proving Ground at White Sands to the Redstone Arsenal, Huntsville, Alabama. At Redstone, they were to develop a new rocket which would become an IRBM (Intermediate Range Ballistic Missile).

2. Naval Research Laboratory (NRL)

A review of the technical feasibility of a satellite led to the NRL conclusion that project would be too large in scope for them at that time.

[19] U.S. Congress. Senate. Committee on Armed Services. Subcommittee on Preparedness Investigation. 85th Congress. 1st and 2d sessions. November 1957, January 1958.
[20] Charter of the Joint Research and Development Board. Secretaries of War and the Navy. June 6, 1946. amended July 3, 1946.

The decision was made to concentrate on upper atmospheric research, using sounding rockets.

3. The Navy Bureau of Aeronautics (Bu/Aer)

Studies of the German rocket program by Bu/Aer were conducted during 1943 and 1944, culminating with the formation of a Committee for Evaluating the Feasibility of Space Rocketry (CEFSR) on October 3, 1945. Its ultimate objective was the launch of instrumented satellites for the purpose of learning the characteristics of the spaceflight environment.

In a sense, the CEFSR was a focal point within Bu/Aer for several hardware projects applicable to advanced rocketry and spaceflight. These projects included the rocket motor development of Aerojet in which hydrogen and oxygen were blended and burned as fuel for the first time.

By the end of October, 1945, the CEFSR submitted its proposed satellite launching program to Bu/Aer. Bu/Aer responded by awarding feasibility study contracts to Guggenheim Aeronautical Laboratory and to Aerojet. Although the results of those studies favored and confirmed the original CEFSR satellite feasibility analysis, the projected cost estimate of the program, set to fall between $5 million and $7 million, was completely beyond anything the Navy would consider.

CEFSR then made a concerted effort to gain support from the Army Air Force for a joint project to develop their single-stage-to-orbit vehicle designated the "High Altitude Test Vehicle" (HATV). The Air Force indicated some encouraging interest but finally turned down the opportunity. The history of the CEFSR effort drew to a close after two additional studies, one by another Bu/Aer group under Abraham Hyatt and another jointly contracted to Aerojet and Glen L. Martin Co., confirmed again the feasibility of the design.

4. The Army Air Force

The Air Force had an interest in satellites but preferred to examine the project of launching one independently rather than as a joint venture with the Navy. They turned to the Project Rand [21] group at Douglas Aircraft.

On May 12, 1946 Project Rand produced their answer, a report entitled "Preliminary Design of an Experimental World-Circling Spaceship." It would demonstrate to the War Department that should the issue of space weapons development arise in the future, the Air Force was at least as prepared for the responsibility as the Navy.

Where advanced technology is concerned, there is sometimes an advantage to being second. The RAND scientists were familiar with the Navy's simple, oxygen-hydrogen HATV. It was a high risk package. Their own approach was to achieve the same performance with proven

---

[21] Project RAND was established in late 1945 and initially operated as a semiautonomous branch of the Douglas Aircraft Corporation, responsible directly to the Vice President, Engineering. Qualified physicists, engineers, and mathematical analysts were drawn from Douglas and other aircraft firms, and assembled at Santa Monica in separate quarters. The original concept was that several companies would get together and set up an advisory type function which, in turn, would allow RAND to advise the various services on what they should procure, so that the services would not request the "impossible" from industry in the area of aircraft armaments. In November 1948, the RAND Corporation was created and became a completely autonomous non-profit research institution.

technology to the extent this was possible. They based their "World-Circling Spaceship on V–2 fuels and technology but added multi-staging. This would more than compensate for their less powerful fuels, reduce the technical gamble and place a 500 lb satellite in a 300 mile orbit within a 5 year period—or by 1951.

The Rand report, perhaps anticipatory of the military judgment that a 500 lb satellite was too small to be considered a potential weapon of destruction, included a number of eloquent and some prophetic justification for its construction.[22]

For example:

A satellite vehicle with appropriate instrumentation can be expected to be one of the most potent scientific tools of the Twentieth Century.

The achievement of a satellite craft by the United States would inflame the imagination of mankind, and would probably produce repercussions in the world comparable to the explosion of the atomic bomb . . .

To visualize the impact on the world, one can imagine the consternation and admiration that would be felt here if the United States were to discover suddenly, that some other nation had already put up a successful satellite.

The Rand report also offered these observations:

1. The booster to launch a satellite is the same as a booster to launch a destructive missile over intercontinental distances.
2. The existence of this technology places the future of manned aircraft operating as bombers or observation platforms in question.
3. The satellite can replace the aircraft as an observation platform.
4. The satellite can also serve as a weather forecasting device and a communications link.

Twelve years later, the 1946 Rand observations were repeated by others during the Senate's 1958 inquiry into the status of the space effort in the United States.[23]

Senator Lyndon Johnson noted that the Sputnik ". . . demonstrates beyond question that the Soviet Union has the propulsive force to hurl a missile from one continent to another." During that year, 1958, General Gavin added his voice [24] to observe:

> The ICBM is the consequence of manned bomber obsolescence . . . not the cause. The manned bomber will become obsolete when effective [armed] surface-to-air missiles can be employed against it . . . as soon as they are on site in numbers.
>
> If manned bombers cannot penetrate enemy territory [in the future] then certainly manned observation aircraft cannot. Observation must be provided by an unmanned reconnaissance vehicle . . . for a short-range missile it will be a recoverable drone operated by remote control; for an ICBM it will, in time, be a satellite.

---

[24] Gavin, General James. "War and Peace in the Space Age," Harper, New York, 1958. 11.

However, in the climate of 1946, no satellite project, joint or otherwise, was to be authorized. There was interest but there was a problem—no clear cut military mission. Another review, completed in March 1948, by The Technical Evaluation Group of the Committee on Guided Missiles, for the Joint Research and Development Board, made similarly negative conclusions, but again suggesting that the studies continue.

F. The First Satellite Plan—1948

The military services underwent a major reorganization with the passage of the National Security Act of 1947. The three services were given equal status in the new Department of Defense. Its first secretary, James Forrestal, in his "First Annual Report of the Secretary of Defense" made a startling announcement in late 1948.

> The Earth Satellite Vehicle Program, which was being carried out independently by each military service was assigned to the Committee on Guided Missiles for coordination. To provide an integrated program with resultant elimination of duplication, the committee recommended that current efforts in this field be limited to studies and component designs; well-defined areas of such research have been allocated to each of three military departments.[25]

This was the first public announcement that the United States was giving any thought to an Earth Satellite. Reactions in the United States were negative—ranging from charges of squandering the taxpayers' money to stronger concerns that the program was an unholy defiance of God's will.[26]

The Russians joined the negative chorus and soundly condemned the program. The Soviet journal "New Times" referred to the "madman Forrestal's idea of an Earth Satellite . . . an instrument of blackmail." [27]

No further official mention of a satellite or satellite program was to appear in the open literature of the Government until November 1954. At this time a press release approved by Secretary of Defense Charles Wilson contained a brief comment that studies continue on the Earth Satellite Vehicle Program. Interestingly, at a press conference preceding this release, the Secretary commented that he was not aware of an American satellite program.[28]

G. Project Mouse (Minimum Orbital Satellite of the Earth)

As studies within the Government continued, interest in an Earth satellite began to spread in the civil sector. Widespread attention to the potential of the space domain resulted from three issues of Collier's Magazine in 1952. Colorful and imaginative illustrations illuminated short essays on space by Werhner von Braun, Fred L. Whipple, Heinz Habber, Willy Ley and others. A subsequent Walt Disney film de-

picting a Lunar flight and showing astronauts manuevering weightless in space, fanned additional interest.

It was also during this period a correspondence began between Werhner von Braun and S. Fred Singer, physicist, University of Maryland. Subsequently Singer was to contribute his imaginative and insightful thoughts at many of the satellite planning sessions, both within and outside of the Government. In 1953 at the Fourth Congress of the International Astronautics Federation, Singer proposed a Minimum Orbital Unmanned Satellite of the Earth (MOUSE). It was based on a 1951 study by the British Interplanetary Society.

Singer's plan was seriously reviewed by The Upper Atmosphere Rocket Research Panel at White Sands in April 1954. In May, Singer presented his plan again, this time to the Hayden Planetarium's Fourth Space Travel Symposium. Thus the public and a growing number of scientists were becoming aware that artificial satellites had outgrown science fiction and were now a feasible part of the real world.

H. The International Geophysical Year (IGY)

The largest military rocket boosters, staged with smaller rockets could place a light payload in orbit, as numerous feasibility studies by Bu/Aer, Rand and others had shown. As mentioned earlier, military support for a small orbiter program was not available in the early 1950's because there was no clear military application. However, there were a growing number of scientific uses for even a small instrumented satellite, and there was a growing interest in launching one. By the early 1950's, the problem was no longer "can it be done" but "how does one go about getting Government support (the launchers and facilities) for a costly program of initially, purely scientific values?" According to Green and Lomask,[29] a group of scientists devised an ingenious and ultimately successful solution. At a gathering at the home of James Van Allen in Silver Spring, Maryland in 1950, which included Fred Singer, J. Wallace Joyce, a Bu/Aer geophysicist, Ernest H. Vestine, geophysicist, Carnegie Institution, Sydney Chapman, an eminent British geophysicist and Lloyd Berkner, head of the Brookhaven National Laboratory, Berkner proposed that another "Polar Year" be established.

The first Polar Year, in 1882, had set the precedent for international cooperation and participation in a scientific project of mutual interest. The focal point would be one or more instrumented satellites capable of observations and measurements of the Earth and atmosphere not otherwise possible. European scientists subscribed to the plan and in 1952 the International Council of Scientific Unions appointed a committee to make the arrangements. It was to last for 18 months instead of 12 and since its effort was to be directed at the entire Earth, the name was changed to the International Geophysical Year (IGY), and would include 67 nations.[30]

The originally established interval of a Polar Year to occur each 50 years was changed to 25 years. The second (and final) Polar Year

[29] Green and Lomask, op. cit. p. 20.
[30] Catalog of Data in the World Data Centers, Vol. 35 of Annals of the International Geophysical Year, Pergamon Press, New York, 1964, vi.

was 1932. Adding 25 years would set the date 1957 for the start of the new IGY, an ideal time because it would coincide with the period of maximum solar activity.

As the planning for the IGY advanced, a goal setting and coordinating group was established, known as *Comite Special de l'Anee Geophysique Internationale* (CSAGI). Lloyd V. Berkner, who could be considered the "inventor" of the IGY, became vice president of CSAGI.

The establishment of an IGY would bring together outstanding scientists of many nations with their myriad of interests. It would not automatically bring approval that orbiting satellites would be its centerpiece. The two major steps in accomplishing that end would be to gain the approval of CSAGI first, then seek governmental support to finance the venture.

By the time of the October 1954 CSAGI meeting in Rome, Russia had joined the IGY. The Russian capability with rockets and their interest in space was known. A. N. Nesmeyanov of the Soviet Academy of Sciences had said on November 1953 that satellite launchings and moon shots were already feasible. In March 1954, Moscow Radio carried materials designed to excite Soviet youth on their prospects for exploring the solar system. The Moscow Air Club announced their own studies of interplanetary flight.[31]

However, at the CSAGI meeting the Russians remained silent observers and watched CSAGI adopt the American proposal to study the Earth with satellites on October 4th. It read:

> In view of the great importance of observations during extended periods of time of extra-terrestrial radiations and geophysical phenomena in the upper atmosphere, and in view of the advanced state of present rocket techniques, CSAGI recommends that thought be given to the launching of small satellite vehicles, to their scientific instrumentation, and to the new problems associated with satellite experiments, such as power supply, telemetering and orientation of the vehicle.[32]

1. The National Academy of Sciences: IGY Committee

The IGY was scheduled to run from July 1957 through December 1958, far enough into the future, it was thought, to devise a satellite, match it to a launching scheme and gain governmental support for the execution of the plan. In January of 1955 the IGY Committee of the National Academy established a Technical Panel on Rocketry—slightly enlarging the original group who had conceived the scheme for the satellite as well as the IGY to make proper use of it. The panel included Kaplan, Odishaw, Newell, Singer, Spilhaus, Whipple, Van Allen, Nathaniel Gerson, Bernhand Hauwitz from the Academy's Meteorology Panel and Geshardt Schilling of the IGY staff. The Panel created a special study group called the Subcommittee on the Technical Feasibility of a Long Playing Rocket (that is, a satellite). It became known as the "LPR" subcommittee and included William H. Pickering, director of the Jet Propulsion Laboratory (JPL), John W. Townsend, assistant head of the NRL Rocket Sonde Branch and Milton Rosen from the Viking rocket project.

---

[31] Green and Lomask, op. cit. p. 23.
[32] Hogan, John D., "The Viking and the Vanguard," Technology and Culture, Vol. 4, no. 4, Fall 1963. 435–437.

The Committee and its "LPR" Subcommittee were to report to the United States National Committee on feasibility, not make actual hardware recommendations. Their report was made on March 9, 1955 and contained no surprises. They saw anyone of the total of these existing options as feasible: a large single stage launcher could be used to place a few small rockets into orbit with little or no instrumentation payload; the three stage launcher could place an instrumented payload in orbit; or the new and larger engine then being developed could power a completely new vehicle capable of carrying a large, well instrumented payload into orbit.

The Committee estimated that any of the three possibilities could be realized within two to three years—placing the launch time within the IGY.

2. The Eisenhower Administration is Approached

The National Academy of Science and the National Science Foundation, even prior to receiving the recommendation of the United States National Committee for the IGY, had begun their role of gaining the support of the Administration.

Following innumerable briefings of various offices directly associated with the White House, President Eisenhower's interest was achieved. The launcher would require an expenditure of equipment, and funds, set aside for purposes of Defense—thus the matter came into the hands of Secretary of Defense Charles Wilson. Wilson was personally disinterested and placed the responsibility for the project with his Assistant Secretary for Research and Development, Donald Quarles, who favored the idea of an IGY satellite.[33]

3. The Stewart Committee

Quarles recognized that there were a number of prospective launchers for which various satellites systems had been proposed with solid feasibility studies to support them. When he found his General Sciences Coordinating Committee favoring the funding of three parallel developments, he appointed an ad hoc "Group on Special Capabilities," generally called the Stewart Committee for its chairman, Homer J. Stewart of JPL.

The group included Charles C. Lauritsen, an eminent physicist and, like Stewart, a professor at Cal Tech. Joseph Kaplan, chairman of the United States National Committee for the IGY, Richard Porter, consultant for Advanced Developments to the General Electric Company's Missile Division, George H. Clement of the RAND corporation, Clifford C. Furnas, Chancellor of the University of Buffalo, J. Barkley Rosser, rocket ballistician and professor of astronomy and head of the McMath Hulbert Observatory at the University of Michigan.[34]

The Stewart Committee made it known almost immediately that they would endorse the IGY satellite launching but would need further study to select the most suitable hardware. This green light allowed a continuation of efforts to pave the way for the program. The numerous Russian statements and internal programs emphasizing space exploration were without doubt a strong asset in obtaining Administration approval.

[34] Green and Lomask, op. cit. p. 35.

4. Eisenhower Announces Satellite Plan July 29, 1955

There was a desire to announce the satellite plan before Russia announced its own plan. Eisenhower agreed to announce the plan even prior to the completion of the Stewart Committee deliberations and, through Press Secretary James Hagerty released the following statement on July 29, 1955:

> On behalf of the President, I am now announcing that the President has approved plans by this country for going ahead with the launching of small Earth-circling satellites as part of the United States participation in the International Geophysical Year . . . This program will for the first time in history enable scientists throughout the world to make sustained observations in the regions beyond the earth's atmosphere.
>
> The President expressed personal gratification that the American program will provide scientists of all nations this important and unique opportunity for the advancement of science.

The President's statement was embargoed until the next day, then released along with statements from the Secretary of Defense, the National Academy and the National Science Foundation.

5. Russia Announces Satellite Plan August 3, 1955

A day later, the Moscow press announced that the USSR would also place a satellite into orbit during the IGY. Moreover, according to the August 3, 1955 New York Herald Tribune, a Russian physicist, speaking of the International Astronautics Federal in Copenhagen, declared that the launch would occur in 1957 and would be much larger than anything the United States would attempt.

The United States had been correct in anticipating the Russian announcement and in terms of this race anyway, had a clear victory.

6. Selecting the Launcher (Stewart Committee)

The Stewart Committee made comparisons of three basic systems: The NRL Viking, the Army Redstone and the new Air Force Atlas system. The Atlas could place a minimal payload of 150 lbs. in orbit and with modest growth, could exceed this by hundreds of pounds. While clearly the Atlas was the most attractive, it was also the least available. Any such program could push back in readiness date as a weapons system, and in 1955, this was not a desirable state of affairs. The choice was therefore limited to the first two possibilities, either of which would put something in orbit but neither were satisfactory without some additional development.

The Stewart Committee deliberated in an atmosphere of intense interservice rivalry, and after making a decision favoring the NRL Viking (to become Vanguard), was reconvened by Quarles only to make the same decision a second time. On September 9, 1955 the official announcement favoring the NRL Viking was released by the Deputy Secretary of Defense, Reuben Robertson. All three services were thus notified that the Navy would be in charge of a joint three-service program.

To General Medaris, Von Braun and others at the Army Ballistic Missile Agency in Huntsville, Alabama, the news came as a shocking blow—difficult to believe. They saw the Vanguard project for what it was, a valiant attempt to build a new and relatively limited launcher under the close to ruinous constraints of an unprecedented development schedule and with under financing.

They knew their established track record in guiding the evolution of their rapidly maturing ballistic rockets could make the satellite project a routine extension of existing capability. They could remove much of the risk from the project. Yet, it was to go in the high risk direction. The reason—a conviction on the part of the Administration that the IGY satellite plan was a clear threat to the tightly scheduled ballistic rocket capacity. Although it was to be permitted, it should be conducted to interfere minimally with defense related programs.

7. Viking Progress and Sputnik

The Vanguard project had no periods of smooth progress. It was conducted under an aura of tension—the ever present concern that Russia would achieve the first satellite. All the evidence available weighed heavily in the direction of a Russian victory in this initial lap of the race into space. Yet, it was not a concern that induced cooperation beyond the most reluctant support of those outside of the immediate Vanguard Operations Group (VOG).

A prolonged struggle was required even to gain a launching area at Cape Canaveral. This struggle set the stage for a continuing effort of seemingly endless trials to achieve a viable launcher. Nothing came easily to the Vanguard Operations Group (VOG). Inexperience was the pervasive enemy, not only within the VOG but throughout the network of contractors and subcontractors. Nothing could be taken for granted and the VOG, working at the Cape, routinely served as quality control for all Vanguard components, virtually becoming an extension of the factory of the Glenn L. Martin Co., prime Vanguard contractor.

III. A NEW ERA—THE FLIGHT OF SPUTNIK AND ITS AFTERMATH

A. Sputnik Appears—October 4, 1957

Within the VOG, the concern that Russia would achieve a successful satellite launch before the United States grew deeper each day, adding frustration to the sure knowledge that haste would invite failure. The intense dedication of the VOG brought the reward of early successes as the series of sub-orbital tests were made to prove each successive stage. A successful test of the complete Vanguard launcher was completed (without the payload or orbiter) during October 1957, and the VOG knew that it had achieved orbital capability.

However, during the conduct of these tests on the third Vanguard test Vehicle (T.V.) which was designated TV–2 since the series began with TV–0, Sputnik was successfully launched.

The race to achieve the first artificial satellite was over—a clear Russian victory. But the race was a close one and the VOG, as well as Von Braun's team at the ABMA now wished to demonstrate that the Russian capability was not unique. A close second place might show this, and reduce the psychological impact of the Russian achievement.

The no-priority project which had been Vanguard shifted quite suddenly into the national spotlight. It became the great hope of the entire Nation. The VOG moved from obscurity into a national goldfish bowl,

suddenly under the scrutiny of the Administration, Congress and the public.

1. Sputnik Alarms Congress and the Administration

Within hours after Sputnik appeared, the Senate Preparedness Subcommittee, chaired by Lyndon B. Johnson initiated an inquiry into the status of the Nation's missile and satellite capability.

Eisenhower requested and received a briefing on the progress and prospects of the Vanguard project as well as the satellite launching capability of the ABMA in Huntsville, Alabama. On October 8, 1957 Eisenhower instructed Secretary of Defense, Charles Wilson to have the ABMA prepare its Redstone at once as a back up to the Navy Vanguard. On October 9th, Eisenhower's press secretary, James Hagarty, announced that the United States planned to launch a "satellite-bearing" vehicle in December 1957.

This vehicle was to be the Vanguard Test Vehicle number 4 (TV–3) which was to carry a "test" satellite. A small 2 kilogram (4.4 lbs.) satellite was to be orbited by T–3, without a scientific payload but carrying a radio transmitter. The news release greatly increased the pressure on the VOG, mostly because an enthusiastic press translated the announcement to read that in effect, in December, the United States would have met the Russian challenge. The VOG was still fighting the quality control battle to launch TV–2, a Vanguard with a live lower stage, two dummy upperstages and no payload. TV–2 had been at the Cape since August and had undergone several complete rebuilding sessions as it failed one checkout after another. Finally, TV–2 was successfully launched on October 23, 1957, clearing the way for TV–3, which would have all live stages plus the small test satellite payload.

2. Viking Test Vehicle 3 Explodes December 6, 1957

The test vehicle TV–3 was known from the outset to be an extremely high risk flight. The second stage engine in particular had never been test fired for the full duration of its thrust period. The vehicle was readied for flight, however, and gave much fewer check out problems than TV–2. On December 6, TV–3 was launched, lifted four feet and fell back in flames. Its spectacular failure was witnessed by an international assemblage of reporters and observers, the largest group ever to assemble for the purpose of witnessing a launch.

Newspapers are seldom kind and headlines related the failure to a further blow to national prestige. Senator Lyndon B. Johnson spoke of the failure as "most humiliating." But perhaps the meanest blow of all came with the offer of aid to the American delegates, from the Russian delegation to the United Nations under the Russian plan to provide technical assistance to backward nations.

3. First United States Satellite, Explorer I Orbits February 1, 1958

The VOG began a harsh schedule to ready the TV–3 back up Vanguard designated TV–3 BU. However a long series of technical difficulties delayed the launch giving the ABMA team a chance to launch successfully their own Explorer satellite.

The initial goal, that of putting a sientific payload in orbit during the IGY had been achieved. However the accomplishment did not signal the completion of a goal. Instead it signalled the entry of the

United States in a highly competitive race with Russia to demonstrate a national capability in the mastery of the new domain of space. Subsequent successful launches and failures were experienced by the Vanguard team and the ABMA, as detailed in other sections of this history. However, neither the public, nor Congress nor even the armed services viewed the combined capability of the two teams as an adequate national effort. The exploitation of the new space domain called for a larger and more permanent organizational structure.

B. Groping for a Way to Manage Space Activities

1. The First United States Space Agency

Shortly after Sputnik, Eisenhower had given interim responsibility for the U.S. space program to the Defense Department. In February 1958, Congress authorized Defense to establish the Advanced Research Projects Agency (ARPA). In March, Eisenhower gave his approval to an interim plan for space exploration which had been advanced by ARPA. Thus in a genuine sense, the first U.S. space agency was a military organization, ARPA.

2. The NACA Plan

Although a number of plans for a civil space agency were advanced in Congress, some as bills, the Administration and most legislators favored giving the well established and highly regarded NACA full responsibility, The urgency, still strongly felt in the Federal as well as the private sector, simply would not allow the time needed to start a totally new agency.[35]

NACA leaders firmly convinced of the superiority of their own committee structure, proposed that their board be enlarged to 17 members; their name changed to the "National Advisory Committee for Aeronautics and Astronautics," and their role and responsibility remain one of the research and assistance to "user" agencies and civil groups.

NACA felt confident that the new space flight research responsibility would be assigned to them. In November 1957, the NACA chairman, Lt. General James H. Doolittle, approved the main committee establishment of a new Special Committee on Space Technology to be headed by H. Guyford Stever. Branching down from the new committee, a group of new subcommittees were to be formed each to handle "special aspects" of space challenge.

In their bid for this new role, the main committee had met in January 1958 and on January 16 published a new resolution on space flight.[36]

The resolution was carefully worded but subject to differing interpretations. Statements were included in which the NACA traditional role would be greatly enlarged to include ". . . Design and development of scientific and military space vehicles and their launching, flight and recovery." However, in later paragraphs, responsibility for the various types of vehicles was "resolved" to be the responsibility of the user agencies. The total thrust of the resolution seemed to suggest a view that the space effort on the part of NACA would be the conduct

---

[35] Levine, op. cit., p. 151.
[36] U.S. Congress. House. Select Committee on Astronautics and Space Exploration. "The National Space Program" House Report 1758, 85th Congress, 2nd session, May 12, 1958.

and coordination of a larger but parallel program patterned after the successful "X" series of experimental aircraft.

Eisenhower and his advisors, especially his newly appointed Science Advisor, Dr. James R. Killian, acting from the conviction that the new space agency should be a civil, or at least a nonmilitary effort, strongly favored turning the responsibility over to the NACA. However, there was a problem or two. First, the committee structure of the NACA did indeed "report to the President" but it was not obligated to him too closely. During its history the NACA had shown itself to be rather refractory to political leadership. There was a question as to whether or not an issue as politically volatile as the new space venture should be relegated to a rather independent committee.

Secondly, the NACA tradition had established its character as more academic than executive. Research, regardless of the quality and responsiveness to the problems of users, did not seem an adequate substitute for executive action and primary responsibilities.

The skills and facilities of the NACA in aeronautics were without equal in the Nation, but something more was needed.

3. The National Aeronautics and Space Administration (NASA) Emerges From the National Advisory Committee on Aeronautics (NACA)

Early in 1958, Eisenhower asked his science advisor, Dr. James R. Killian, Jr., to formulate a plan leading to an adequate civil space agency. Killian, in conjunction with experts in administrative organization, such as William M. Finn of the Bureau of the Budget, submitted a recommendation to Congress in the form of a draft bill on April 4, 1958.

The latter months of 1957 and early part 1958 was a period of confusion and competition throughout the Congress and in all executive agencies having aspirations to take a role in exploiting the new space domain. Bills proliferated as congressional champions of various agencies sought to secure new scientific and space related functions for a favored agency.

Levine's [37] account of this period puts the evolving NACA plan in context with some of its rivals.

> The leaders of NACA were among those diligently and rapidly working on the preparation of a proposal for the assignment of the space role. Their first step followed the traditional lines of NACA procedure as they established a special committee on space technology, headed by H. Guyford Stever, Associate Dean of Engineering at MIT. This was on November 21, 1957. Less than two months later, the Main Committee of NACA adopted a resolution recommending that the national space program could be most effectively implemented by a cooperative effort of the Department of Defense, the NACA, the National Academy of Sciences, and the National Science Foundation, together with universities, research institutions and industrial firms. Under the NACA plan, the military would be in charge of development, construction and launching of space vehicles, while the NACA would have responsibility for research on satellites and scientific experiments in space.

This was a simple solution for the NACA since it merely elaborated on its existing procedures, contacts and close rapport with the military.

Competition for the proposed NACAA included bills to turn space exploration over to the Atomic Energy Commission, the National

---

[37] Levine, op. cit., p. 146.

Science Foundation as well as totally new agencies, one to be called the Commission on Outer Space. Another new entity was proposed in two bills to be called the Department of Science, an umbrella for science, parts of which would cover space.

Even more comprehensive were bills proposing a new Department of Science and Technology which would subsume existing agencies such as the National Science Foundation, the Atomic Energy Commission, the Bureau of Standards and the NACA.

The Department of Defense, being the owner and manager of the Nation's existing space capability was also a rival. In February, 1958, the Defense Department, with the authorization of Congress, created the Advanced Research Projects Agency (ARPA). This organization was brought into being expressly to direct and manage future space exploration. The month following its creation, ARPA received the President's approval to go ahead with its plans for space exploration. Thus ARPA became the Nation's first space agency. However, the ARPA role was transitional. As Levine [38] described it:

> Despite this development, it was clear that the Administration did not intend to give the Defense Department the science space role on a permanent basis. The President was trying to establish an agreement with the Soviets that "outer space should be used only for peaceful purposes." He did not wish to jeopardize this position by designating a military agency as the Nation's chosen space pioneer. Rather he felt that the U.S. scientific space program should be conducted by a civilian agency. In this view he was strongly backed by both his political and science advisors. As a result of this strong Presidential preference, the Defense Department was never really in the running for the science space role, and proposals for giving the space research job to the Defense Department were discarded early in congressional consideration of this matter.

4. The Administration Favors NACA

The Administration's desire to place the responsibility for space in the hands of civilians gave the NACA confidence that it would become the Nation's space agency. However, the NACA structure was such that its operating head was selected by its committee. There would be no single executive in charge of the space effort whose tenure would be in the hands of the President. Under the NACA organizational practices, the President would have only an indirect control over an activity for which he would be responsible. This was not considered an acceptable arrangement, and work was begun on a Bill to establish a new space agency, headed by a single executive and which would absorb the NACA.

NACA leaders disturbed over this initiative, and convinced that their 40 years of operating experience had proven the merit of their committee structure, sought and obtained Congressional support. As summarized by Levine: [39]

> Disturbed by the way the Administration bill was developing, NACA leaders requested friendly Congressmen to introduce measures which would give NACA the space role, while preserving the traditional NACA organizational pattern. As a result, in March and April 1958, bills were introduced by Representative Frelinghuysen (Republican—New Jersey) and Senator Francis Case (Republican—South Dakota) giving the responsibility for outer space development to NACA. Both bills would make slight alterations in the name of the agency, but would leave undisturbed the arrangement whereby the agency would be governed by a 17-man board appointed by the President and a Director appointed by the Board.

---

[38] Levine, op. cit., p. 149.
[39] Levine, op. cit., p. 155.

The "NACA bills" were introduced much later than "rival bills" which would give the space role to the AEC, NSF, or to a new department of science. This fact did not help congressional considerations of the point of view of NACA leaders. The NACA viewpoint was dealt a severe blow when on April 2, 1958, President Eisenhower sent a message to Congress proposing the establishment of a new agency, the National Aeronautics and Space Administration, into which NACA would be absorbed, and under which the 17 man board would be down-graded to an advisory status only. Henceforth, as members of the Administration, leaders of the NACA would be obliged publicly to concur with the President's prescription for the organization of the new agency.

After the Administration bill was introduced, on April 14, 1958, it became increasingly clear that the Administration proposed to change not only the organizational structure of the NACA but proposed as well what would really be a new agency, with NACA as its nucleus, rather than an enlargement of the old aeronautical research group. The new agency would not only have a single executive, but it would be a powerful operating agency as well, with significant authority for contracting for the building of "hardware" and for systems development, for launching satellites and other space vehicles, and for transfer of use of other government facilities that could contribute to the space program.

In brief, the Administration bill placed the total responsibility for the civilian space program in the hands of a single agency. The NACA proposal would divide the responsibility among the interested agencies and the military.

IV. PERFECTION AND PASSAGE OF THE NATIONAL AERONAUTICS AND SPACE ACT

A. Congress Examines the Administration Bill

The congressional jurisdiction for space was widely claimed. Hearings had begun in 1957 by a number of committees including the Senate Preparedness Investigating Subcommittee of the Senate Armed Services Committee, both Senate and House Appropriations Committees, the House Armed Services Committee and the Special Subcommittee on Outer Space Propulsion of the Joint Committee on Atomic Energy.

By February 1958, the Senate had established a Special Committee on Space and Astronautics. The House also centralized its interest by creating its Select Committee on Astronautics and Space Exploration.

The two dedicated space committees intensively examined every aspect and ramification of the Administration bill, and, working independently, extensively rewrote it. Many measures they dealt with, such as patents and foreign relations, had little bearing on the scope or organization expressed in the bill. However, other modifications did, such as the structure of the new agency, its power and its relationship with the military. Identification of the major points of departure between the Administration bill and the Congressional Committees, and their resolution was synthesized by Levine as follows: [40]

1. Organizational Structure

The organizational structure proposed by the Administration puzzled many members of both the House and Senate Committees. The Space Board outlined in the Administration bill seemed to these members to be neither fish nor fowl. The Board generally would have advisory powers only, yet it seemed that it might overshadow the Director of the agency in some respects. There was, for example, a requirement that the President must give the Board "a reasonable

[40] Levine, op. cit., p. 165.

opportunity" to recommend nominations for Director of NASA before he appointed a person to that post. Other provisions in the bill required that the Director consult with the Board before he initiated or substantially modified policies or programs, transmitted requests for appropriations to the Bureau of the Budget, established major constituent organizational units of the Agency, assigned major functions, or appointed heads of major constituent units. In addition, the Administration bill provided that the Board would make an annual report to the President, and such other reports as it deems appropriate, and would generally advise the President, as well as the NASA Director.

The composition of the Space Board bothered some members of the Congressional Committees. The Administration bill provided that the Space Board should have seventeen members of which "no more than eight . . . shall be designated from appropriate departments and agencies of the Government of the United States, including at least one who shall be from the Department of Defense." Other members of the Board must be non-governmental and would be appointed because of their eminence in "science, engineering, technology, education, and public affairs, and shall be selected solely on the basis of established records of distinguished achievement."

Two things about the make-up of the proposed Board were disturbing to some House and Senate Committee members. First, non-governmental members would be in the majority by at least 9 to 8. Indeed, the non-government majority could be greater, since the language of the bill made it mandatory that only one Government representative—from the Defense Department—be appointed. The other seven posts, while seemingly reserved for members from the government, could be given to persons from private life without violating the provisions of the bill. Some Congressmen feared that the Board might be dominated by special industrial interests unless provision was made for a clear Governmental majority. The NACA Main Committee, they pointed out, had a Governmental majority from its inception.

The other cause of concern to some of the legislators was a lack of representation from the Defense Department on the Space Board. Military interests and effective liaison by NASA with the services would be neglected unless the Defense Department participation in the Space Board was bolstered, they felt.

As a result of these twin concerns, the House Committee amended the Administration Bill to provide that 9 of the 17 members must be drawn from the Government, and to provide that three of the Space Board members be from the Defense Department.

2. Status of NASA in Executive Branch

Both the Senate and House committees which were studying the Administration bill were concerned that the proposed space board would be ineffective. There would be a lack of executive power. The Senate committee proposed the creation of a high level Space Policy Board, eliminating the Administration's proposed Advisory Board.

Its seven member Space Policy Board, operating from the Executive Office of the President would include the NASA Director, the Chairman of the AEC, as well as the Secretaries of Defense and State. The remaining three members would be designated by the President.

The House committee proposed a more direct, simpler solution. It would greatly increase the authority of the Director and give him direct access to the President.

3. NASA Military Relationship

Both the Senate and House committees saw that the Administration bill left the NASA-military relationship as an informal and flexible arrangement. For example, NASA, should it choose to do so, could limit itself to research and turn all hardware development tasks, including those of a strictly civil nature, to the military.

The Senate committee reacted to this by carefully defining the jurisdiction of NASA and the Department of Defense and placed coordination authority in its proposed Space Policy Board. The House

committee also amended the wording of the Administration's bill and established a military liaison committee which would consist of personnel from the Department of Defense.

4. A Conference Committee Resolves Differences

The creation of a Space Policy Board, appearing in the Senate version but not in the House version was amended to include the President as chairman, an eighth member. Its name became the National Aeronautics and Space Council. It was expected by Congress to be a policymaking and coordinating body of major significance, associating the President himself as a responsible source of policy for the space program.

The military liaison concept of the House version was also retained in a modified but broadened form. Called the Civilian-Military Liaison Committee, it would have an equal membership from NASA and from the military.

The Administration proposal for an Advisory Space Board was stricken from the bill.

The concern of both committees that NASA would have the freedom, should it choose to use it to limit its activities to research and look to the Defense Department for all development and operational pursuits was met by altering the language in the "Declaration of Policy." NASA was given responsibility for aeronautical and space activities except those associated with defense. The word "activities" was substituted for the word "research" which had been used in the Administration version.

The Administrator of NASA was required to be a civilian and was given wide operational powers.

The changes in the Administration bill reflected the concerns of both the House and Senate "space" committees that the broad scale activities to be undertaken by the new NASA; the world wide tracking activity, the development and use of spacecraft—eventually manned exploratory vehicles, would be beyond the capability of an agency structured to be merely an extended NACA. They felt that the NACA, even though it was a respected scientific establishment, lacked the experience to do contracting and managing on the scale expected.

The Report of the House Committee issued in May 1958 illustrates this point: [41]

> No one can question the great contribution NACA has made to United States aviation and to the first phases of space inquiry. Its director, Dr. Dryden, is a scientist of proven ability, as is his staff. They have the advantage of long experience in working with the military. The great majority of scientists questioned have expressed approval of its choice as the nucleus of the new space agency. The nature of the approval, however, and the qualifications expressed, have varied greatly. The Air Force, which has long worked hand in hand with NACA, has been especially emphatic in its praise. Major General Bernard Schriever, in his testimony, saw NACA taking over the space effort with a little greater authority and a broader scope of responsibility. As General Schriever expressed it, the NACA is the perfect "building block" for the new agency.
>
> Other witnesses found NACA, in its present form and tradition, something of a stumbling block as well. Their objections stemmed principally from the apparent official confusion of what NACA is doing, and has been doing, and what

[41] U.S. Congress. House. Select Committee on Astronautics and Space Exploration. "The National Space Program" House Report 1758, 85th Congress, 2nd session, May 12, 1958. 12–14.

the space agency is supposed to do, must in fact do, if the effort is to succeed. NACA, as now constituted, is a research agency, with the traditions of a research agency. It has acted through the years as a sort of extraordinarily valuable problem-solver for the services and for civil aviation. But all of the problems it has solved have been technical. Although NACA is very definitely, as Dr. Dryden put it, an operating organization, its operating traditions have all been consultative, advisory, mediatory.

This points up a considerable problem. It would not be a serious matter, perhaps, that the NACA, as constituted, has no tradition of developing hardware behind it. (Its mode of advance into the space field has also cast some doubt on the reservations of rocket experts who felt that aerodynamics and aeronautics are two separate disciplines.) But the lack of any tradition of direction and coordination could be very serious. This is a problem by itself. Without drastic sweeping changes, it is no mean feat to inculcate a spirit of decision-making in an organization that has lived and thrived on a tradition of peaceful advice-giving. And any space agency, by the urgent nature of its mission, by the inevitable commingling of civilian and military in many fields, will have to know how to rap knuckles.

Also questioned by both the House and Senate Committees was the ability of an extended NACA to deal effectively with the powerful military and industrial groups, each with its special interests. Witnesses from these groups, such as Assistant Secretary of the Navy Garrison Norton, General Schriever, General Putt of the Air Force, and Deputy Defense Secretary Quarles, testified to their lack of concern on this project, and affirmed their high regard for the administrative strength and integrity of the NACA type of structure.

Congressional doubts about how well a NACA type organization would fare in the real world brought about changes in the Administration version as well as a rejection of the NACA recommendations. Congress accepted the idea that the NACA would provide a good technical foundation but its organizational concepts, even as modified by the Administration bill, would not equip NASA for successful pursuit of the space program.

The reconciliation of the House and Senate versions of the NASA bill by the conference committee was a difficult and stormy battle. Nearly a month was required, during which communications between the House and Senate Members ceased on occasion. However, agreement was achieved and the conference version was produced on July 16, 1958. President Eisenhower signed the bill on July 29, 1958.

Thus, an administration for space was established, including mechanisms for adjudicating possible, in fact expected, conflicts between NASA and the Defense Department via the National Aeronautics and Space Council and the President.

V. NASA: 1958–1979

A. Administrators

Although the enabling legislation for NASA was not law until October 1, 1958, activities to convert the NACA into NASA began in March. There was a pressing urgency in Congress to see that the new space agency would have a running start. The selection of an Administrator did not become an area of controversy until July. NACA personnel had assumed that their own Director of Research since 1947, Dr. Hugh L. Dryden, would be appointed. Feelings in Congress were

not as unanimous.[42] Some Congressmen felt that the desired level of vision and aggressiveness would not be found in a veteran career employee. However, Dryden was highly regarded by Congress generally.

On August 1, 1958 during his otherwise very acceptable testimony at the hearings on the "Space Act", Dryden made a derisive comment on Von Braun's proposal to place a manned spacecraft on a Redstone missile for a ballistic flight of a few hundred miles. He quipped that "such a flight has about the same technical value as the circus stunt of shooting a young lady from a cannon." Following a number of quick objections to his remark, he made an unsuccessful effort to explain, then retract his comment. But he had indelibly underlined the label he already carried, that of a conservative albeit respected scientist.

Eisenhower then asked Killian, his science advisor, to locate another candidate. On August 7, Killian, with Eisenhower's approval, asked Thomas Keith Glennan to come to Washington to discuss the position. Eisenhower offered Glennan the position and Glennan accepted.[43]

1. Glennan

Thomas Keith Glennan (August 19, 1958–January 20, 1961) came to NASA from the presidency of Cleveland's Case Institute of Technology, a position he obtained in 1947. Born in 1905, he received a degree in electrical engineering from Yale. Prior to World War II, he worked for the motion picture industry as a sound system specialist. During the war, he headed the Navy's Underwater Sound Laboratories. His tenure at Case included service on numerous Federal and industrial advisory boards among which was a term (1950–1952) as a member of the Atomic Energy Commission.

Glennan's nomination as Administrator along with Dryden's Deputy, were received by the Senate Special Committee on Space and Astronautics on August 9th. Full Senate confirmation came on August 15th. Glennan and Dryden were sworn in at the White House on August 19, 1958.

Glennan's prior history left the question open as to his boldness as a leader and Administrator. The burden of management grew steadily in the early months and become even greater after the passage of the Space Act in October.

NASA's rapid growth and growing diversity led Glennan to seek help in organizing it. He contracted with the Washington office of McKinsey and Co., a management consulting firm, to make an organizational study and model which could be used as a long term guide for structuring the agency.[44]

Meanwhile, Congress and the Nation waited, not too patiently, for some bold moves. Then in July 1959, Glennan took his turn to explain his view of the NASA role to Congress. To their dismay, they heard Glennan say, "Basically we are a research, development and exploration group . . . Now we do not conceive our job as taking us into

[44] Rosholt., op. cit. p. 42.

operational systems, but perhaps to the prototype . . . but not beyond that . . ." Gibney observed, "This was hardly the sort of big thinking that Congress was quite plainly hoping for. The 1958 space law stated clearly that NASA should direct 'space activities' of the United States except for . . . weapons development." [45]

Glennan, it turned out, shared Dryden's approach to management. He was cautious and methodical—definitely not about to leapfrog his way into space, whatever the state of the Russian program. He settled instead for the less showy but no less vital task of amalgamating the diverse programs, personnel and facilities transferred into NASA with the core group, the NACA. None of these parts and pieces including the NACA had ever functioned before as a fully responsible independent operating agency. Glennan presided over the formation and emergence of an operating, nationally and internationally responsive agency. Glennan's tenure at NASA was therefore a hectic and trying period; a time of organizational evolution; a time of realignment of subgroups and reassignment of personnel; a time of structuring both internal and external relationships. Possibly it was not an appropriate time to add the bold moves into space, the hoped for leap frogging of the Russians accomplishments. Also, such moves may have been technically impossible.

NASA's launch record during the 29 months of Glennan's administration shows only eight successful launches out of 25 attempts. Through this period, the success rate improved steadily reaching 50 percent during 1961.[46] Launch vehicle reliability was the problem, not the failure of satellites to function once placed in orbit.

Glennan's legacy to his successor, James E. Webb, was a large one. NASA had become a capable and functioning agency. Reliability programs, long range planning, executive training were established functions. The coupling of the Nation's industrial and university sectors to NASA goals and requirements had been accomplished. Finally, the general management of NASA had been uncoupled from the work load of the Administrator by creating the post of Associate Administrator.

2. Webb

James Edwin Webb (February 14, 1961—October 7, 1968) was nominated by President Kennedy on January 30, 1961 along with the announcement that Hugh L. Dryden had been asked to remain in his Deputy Administrator's position.

The Senate Space Committee acted immediately, holding hearings on Webb's nomination on February 2, several days prior to their formal notification. Lyndon Johnson favored Webb over a number of outstanding "technical" men. He believed NASA would be best served by a tried and expert administrator.[47]

Born in 1906, Webb received a degree in education from the University of North Carolina and then a law degree from George Washington University and an admission to the bar. His career revealed him to be a dynamo of activity, highly successful and respected in the

[45] Gibney, Frank; Feldman, George. "The Reluctant Space Farers," New American Library, New York, 1965. 79.
[46] Rosholt, op. cit. p. 175.
[47] Rosholt., op. cit. p. 187.

field of aerospace as well as in government. After a seven year term with Sperry-Gyroscope, he served in World War II becoming a major in Marine Corps aviation. From 1946 to 1949, he was Director of the Bureau of the Budget, moving from there to Undersecretary of State for three years. At the time he was nominated for the NASA post, he was a director and officer of Kerr-McGee Oil Industries, a director of McDonnell Aircraft and Chairman of the Municipal Manpower Commission. Webb agreed to withdraw from any firm doing business with NASA.

The Space Committee enthusiastically endorsed him and the Senate confirmed him on February 9, 1961. He was sworn in on February 14. NASA had a new type of leader, an unusual man whose forte was administration but who was grounded in law and whose natural element was high technology and aerospace in particular. Added to this was his well established working rapport with the entire executive branch, his first hand familiarity with the Nation's international relationships and his experienced liaison with congressional leaders.

Webb presided over NASA during its period of maximum growth and maximum capability. As Teague [48] put it, when he heard that Webb was resigning:

> Jim Webb has met the test of great responsibility and the demand of leadership . . . he can leave NASA with a realization that he had established the greatest technological team that the world has ever known—a team well capable of reaching the goals which have been set forth.

For personal reasons, Webb departed from NASA nine months prior to the first lunar landing. He left at a time of high personal standing with both the Administration and Congress, closing an extraordinarily successful eight year tenure.

3. Paine

Thomas O. Paine (March 5, 1969–September 15, 1970) was appointed Acting Administrator of NASA by President Lyndon Johnson a few days after Webb's October 7, 1968 resignation. Following President Nixon's nomination, Paine was confirmed as Administrator on March 5, 1969. Born November 9, 1921, he received a Ph. D. in Physical Metallurgy from Stanford in 1949.

During World War II, he served as a submarine officer in the Pacific and was awarded the commendation medal and submarine combat insignia with stars.

Following the war he held a succession of scientific research positions with the General Electric Company. For the five years prior to accepting the NASA position, he was manager of Tempo, G.E.'s Center for Advanced Studies in Santa Barbara, California.

Much solid work emerged during Paine's tenure at NASA. In aeronautics, the "supercritical" wing entered the flight testing stage and produced dramatic changes in traditional concepts of airfoil and wing design. The new wing section, being quite thick, produced wings with greatly increased internal volume, making possible significant reductions in structural weight. The greater lift generated by the new wing made possible wing area reductions of up to 30 percent.

---

[48] Olin (Tiger) Teague, Chairman of the House Committee on Science and Technology.

Reductions in drag were made possible not only because of the more efficient shape but also because of the reduced wing area. But, whatever their importance, achievements in aeronautics were pale indeed compared to the space spectaculars which were to mature during Paine's tenure.

Apollo 11, the first human visit to the Moon was an historic event totally without precedent in man's experience. The event could be observed in real time around the world.

For all its grandeur and promise, the lunar landing was an anti-climax to those whose major concern was victory over Russia in the conquest of space. The event and the landings subsequent to Apollo 11, did not alter the downward trend in the NASA funding—a trend which began prior to Webb's departure.

The highlights of the period were rewards from investments made in the past. NASA had entered a period in which investments for future events were becoming increasingly austere.

The NASA budget had declined rapidly between 1966 and 1970, averaging $500 million per year. The number of people employed on space projects had declined from 420,000 (1966) to 190,000 in 1970.

Paine's administration was characterized by contrast. The world could watch the maturing spectaculars while internally the prime task was to minimize the rising costs of deferrals and the losses from cancellations.

Dr. Paine resigned September 15, 1970 to return to the General Electric Company.

4. Fletcher

Dr. James C. Fletcher (April 27, 1971–May 1, 1977) was sworn in as NASA Administrator in President Nixon's office in April, having received his Senate confirmation on March 11. Born June 5, 1919 in Millburn, New Jersey, Fletcher attended public schools in Flushing and Bayside, New York. He received his undergraduate degree from Columbia University in 1940 and his doctorate from California Institute of Technology in 1948.

Dr. Fletcher came to NASA from the University of Utah, where he had served as President since 1964. Prior to that he had a distinguished career in the aerospace industry. He was Director of Hughes Aircraft Co. Theory and Analysis Laboratory for six years, leaving in 1954 to become Director of Electronics for Ramo-Wooldridge Co. where he served for four years. In 1958, he organized and headed the Space Electronics Corporation. In 1961 Space Electronics merged with Aerojet to form the Space General Corp. where he served as President and later Chairman of the Board, as well as Systems Vice President of Aerojet General Corp. Then in 1964, he accepted the Presidency of the University of Utah.

Fletcher accepted the reins at NASA when public enthusiasm and worldwide awe was still high. Just two months prior to his swearing-in ceremony, Apollo 14 had successfully completed the third manned lunar landing. Apollo 15, which carried the Lunar Roving Vehicle, completed its spectacular success during his third month. This was followed by two more Apollo flights, completing the Apollo program. Along with these came the unmanned visits to Mars in the Mariner

series, the visits to Jupiter in the Pioneer series, the launching and triple visits to Skylab the last of which lasted nearly three months.

The era of space spectaculars for NASA, great enough to entrance the world, began in 1969 with the first Apollo lunar voyages. It was at its peak when Fletcher began his service in 1971 and received a slight boost in 1975 with the Russian-United States Apollo-Soyuz Test Project, a mutual docking of the two spacecraft in which coupled air locks could be opened as a passageway between the ships.

The worldwide enthusiasm over man's first departures from Earth and his first visitations to the newest and certainly the largest of frontiers, was not shared in Congress. The declining budget and shrinking activity in NASA had begun prior to Fletcher's arrival and continued as a trend throughout his tenure.

If Fletcher's administration was distinguished as the longest sustained period of manned and unmanned exploratory adventures in space, it was also significant as the era in which the actual design and construction of a lower cost space transportation system began, the space shuttle.

NASA planners had talked about a type of spacecraft which could be used repeatedly like an airplane from the earliest days of the space program. There was no prior art on which to base such a craft in contrast to the maturing art of building larger and larger rocket powered missiles. During the early days the driving urgency was to achieve space flight and then to meet the goal set by President Kennedy to achieve a lunar landing prior to 1970. The missile origins were therefore expanded through all the families of space boosters finally culminating with the Saturn V which drove the Apollo spacecraft.

During Fletcher's administration the urgency changed directions. While the work done to develop the single use boosters and single use payloads was paying off, NASA saw a dramatic increase in practical space applications covering worldwide communication systems, meteorology, earth resource surveys, scientific stellar and solar observations as well as military surveillance satellites and navigation systems. They also saw these applications favored by Congress over the more spectacular lunar and planetary voyages. If the real value of the new domain of space was to mature, a less costly means of transportation seemed essential. The urgency that seemed always present in NASA therefore shifted toward the development of a varsatile "truck" which could service the areas of space most critically important to the near term future—the near Earth orbits. This reusable space transportation system, called the shuttle, would also serve as a launch platform for the auxilliary boosters used to reach the higher orbits of the synchronous satellites.

Fletcher presided over the culmination of NASA's initial space effort, the era of expendable boosters, and also the planning and start of the transition to reusable space transportation systems. When Fletcher resigned in May of 1977, the first shuttle orbiter was completing the captive phase of its test flights, being carried on the back of a Boeing 747.

5. Frosch

Dr. Robert A. Frosch (June 16, 1977–Present) came to NASA from his position as Associate Director for Applied Oceanography at the

Woods Hole Oceanographic Institution, Cape Cod, Mass., a position he had held since 1975.

For the two years prior to that Dr. Frosch was Assistant Secretary General of the United Nations as well as Assistant Executive Director of the United Nations Environmental Program. Previously, from 1966 to 1973, he served the Government as Assistant Secretary of the Navy for Research and Development.

Frosch's tenure, like the latter part of Fletcher's, has lacked the drama of manned space adventures, but has been ornamented with rich returns from the unmanned planetary probes. The center piece has been the continued development of the shuttle, which made its first free flight, a release from a Boeing 747 and a glide to landing, during his third month in office.

The agency has continued its decline in size and spending power, but has succeeded in protecting the continued development of the shuttle, which is now expected to make its first test flight during 1981.

B. Budget

The appearance of Sputnik in 1957 came as no surprise to the hard working team of United States scientists and technicians striving to prepare a launcher and satellite for the International Geophysicial Year. As detailed earlier in this chapter, Sputnik did not surprise the Army Ballistic Missile Agency either. They were dismayed but knew they were in a race for the first Earth Satellite. However, the rest of the world, along with the United States Congress was stunned.

Any idea that the creation of a satellite for scientific purposes was in accordance with the goals of the IGY was totally eclipsed by a deep concern for national security. Russia appeared to have dramatically achieved a new scientific and military prowess far beyond that of the United States.

The budget appropriations shown in table 3–1 are graphed in figure 3–1. The mood in Congress is clearly illustrated by the rapid rise in funding. Relative buying power through the years is illustrated by the heavier line labeled "Constant Year (1967) Dollars".

TABLE 3-1

Shortly following the Presidential decision and announcement that the United States would visit the lunar surface, a series of manned orbital flights (Mercury) was achieved. These flights clearly indicated that the Russians' prowess in space was not unique. The United States also possessed the science and ability to launch men into space. In terms of funding, hence congressional concern, the Mercury flights coincided with a more relaxed feeling toward space achievements.

Funding began to decline just prior to the next series of manned orbital flights, the Gemini series. It dropped precipitously during and following the Gemini series and continued to decline during and following the Apollo lunar flights. From 1974 to the present, funding in terms of buying power has remained flat and equal to that received by the agency in 1962, the fourth year of its life.

If funding of an agency is used as a barometer to gauge congressional interest, it would appear that in the six years following Sputnik, there was indeed a space race. However, getting a man on the Moon, the Presidential commitment of 1961, would not appear to be of great congressional interest. Once the earliest orbital flight program drew to a close, interest in Congress waned rapidly and no amount of world acclaim or scientific return could reawaken it.

Then, with the general acceptance of the shuttle as a means of reducing the cost of Earth-oriented payloads and placing them in space, the budget flattened.

Manpower, in terms of total employment (figure 3–2) almost duplicates the shape of the funding curve. Beneath the total employment curve a NASA personnel line has been plotted. (See table 3–2 for the actual numbers.)[40]

* Includes Temporary Personnel

a/ Excludes 859 employees in the youth programs.
b/ Includes 592 of ERC which closed 6/30/70.

Employment within NASA peaked at 35,860, coinciding with peaked funding, then declined somewhat more slowly than the funding decline. In 1978, personnel strength matched the 1962 level whereas funding, in terms of buying power matched the 1962 level in 1974, then held constant through 1979.

The labor intensive nature of NASA contracts—the cut and try of development work and the hand built finished products results in the nearly perfect fit of the funding curve and the total employment curve. The comparison of these curves clearly illustrates the extent to which NASA served as a manager to the far larger effort conducted by the private sector. The ratio of NASA employees to those in the private sector was one NASA employee to ten in industry during peak funding. As funding declined, the ratio reached to one to four in 1974 and has remained fairly constant since then, again matching the 1962 personnel strength and NASA employee to private sector employment ratio.

VII. SUMMARY AND CONCLUSION

A. Management Issues

Viewed from the outside, NASA, in its conduct of the space program, gave the impression of a superbly unified management machine. Within a single decade, the largest undertaking in history, the lunar flights, had been started and completed. Satellites of many kinds opened entirely new dimensions in communication and practical studies of earth, its resources and its meteorology. Astronomy, no longer Earth-bound, entered a new era. The staid dignity of this most ancient science was replaced with the high drama of fresh and continuous discovery. The growing uses of the new domain and the advances required to reach and use it represents a common interest, perhaps the only bond between all the nations on Earth. During the second decade, all but a handful of nations became direct participants or partners with other nations in some space related venture.

Viewed from the inside, NASA's management machine was far from unified. While history testifies to the general soundness of NASA decisions, they arose more as final vectors from many internal and often external forces. Some of the salient management issues can be readily identified. They provide a rough overview of the NASA managerial environment.

1. Cooperation of NASA Research Centers—An Issue Solved by Money

Before the signing of the Space Act, both Houses of Congress, among others, expressed serious doubts that the NASA could make the transition from its long history of being a militantly independent, loosely affiliated body of research scientists and consultants to the required highly disciplined, mission oriented body under the control of a responsible executive. Would the NASA centers forego their tradition of autonomy and accept the discipline of executive leadership? That was the big question.

The repetitive appointment of Dr. Hugh Dryden as number two man in NASA, either as Deputy to the Administrator or as Chief

Scientist almost insured a negative answer. It was Dryden's frequently stated belief that executive control would end creativity. Yet without executive control, the Centers would not accept, at least in a timely manner, the congressional intent of gaining access to the space environment to an extent at least equal to that demonstrated by the Russians. Thus the dilemma.

Money was not a restraint during NASA's first eight years and this circumstance led to an elegant and effective solution. The Administrator would subject the Centers of the former NACA to the pressures of cooperation rather than the obedience of executive leadership. There were enough unanswered, yet vital research questions to justify those Centers' operation under a division in NASA to be called the Office of Advanced Research and Technology.

Funds were available to establish new Centers, which would be totally dedicated to the space mission from the outset. These would respond to the two pronged attack on conquering the space environment under two additional executive officers, the Office of Manned Space Flight and the Office of Space Sciences.

If internal conflict, competition for funds, an occasional resignation-in-protest, can be attributed to the vigor and growth of the organization, NASA's solution was a way to the best of both worlds. The powerful research capability of the NACA was preserved. There was no longer a danger that creativity would be squelched nor that the demands and scheduling associated with a mission orientation would usurp the funds or talent of a longer range research effort. The research centers would continue their work in aerodynamics and other fields but would also become assets to the tightly scheduled mission oriented centers.

2. Technology Transfer

The NACA predecessor to NASA had a chronic difficulty in transferring new technological developments into the private sector for practical application. NASA policy has been aggressively to pursue all practical means of rapidly transferring or making available new technology to the public or to potential users. This is done through a variety of periodical publications, press announcement and consulting services.

Although the process of technology transfer is an important activity in NASA, the problem is not the same as it was in the NACA. The greater part of NASA's development work has always been conducted by the private sector under a contract or grant arrangement rather than in a government laboratory as was done by the NACA.

As mentioned in an earlier section, driving NASA's peak years, there were from 10 to 12 people working in NASA projects for every NASA employee. This ratio declined as funding decreased but remains at a 4 to 1 ratio today. Thus, for a major portion of NASA's contribution to advanced technology, the problem of technology transfer was eliminated. It was automatically in the private sector because it was developed there.

Research in aeronautics presents a special case, since a significant portion is still conducted in-house. The great financial risk in aircraft design and production insures a cautious, conservative approach; an

atmosphere in which innovation is seen as a potential threat to survival.

The NACA, almost from the time it was created, sought solutions to transferring its findings into practical application. Theoretical findings, even with wind tunnel testing, seldom aroused the enthusiasm of the industry. Years before the formation of the NASA, the NACA adopted a policy of flight demonstration of innovative aerodynamic design, propulsion systems and demonstrations of new structural and material developments. It was labeled the "proof-of-concept" approach and would bear the high risk of moving a concept from its theory stage into the real world of flight application. With this risk absorbed, the industry could afford to regard innovations in a less fearful way.

The "proof-of-concept" philosophy was continued under NASA and is in effect today. It has been augmented by contract work in which a conventional aircraft is modified and tested by its manufacturer.

Equally important in the technology transfer process is the policy of service available to manufacturers who are developing a new design or who may be modifying an existing aircraft. In addition to consultation, NASA wind tunnels and other research facilities are available to the private sector on a reimbursable basis.

3. Civilian Goals vs. Military

NASA's enabling legislation, the National Aeronautics and Space Act of 1958, expresses the intent that NASA activities should be directed toward peaceful pursuits. Objectives number four and five are explicit on this point:

> (4) The establishment of long-range studies of the potential benefits to be gained from, the opportunities for, and the problems involved in the utilization of aeronautical and space activities for peaceful and scientific purposes;
>
> (5) The preservation of the role of the United States as a leader in aeronautical and space science and technology and in the application thereof to the conduct of peaceful activities within and outside the atmosphere.

The commitment to the pursuit of knowledge and goals for peaceful applications introduced a number of dilemmas, conflicts and continuous requirement for caution in all public statements. For one thing, a bit of new knowledge is usually as valuable to military pursuits as it is to peaceful ones. New knowledge in the aerospace sciences may be of long range interest to peaceful applications but of immediate value to the military. The following elements gave rise to a wide zone of ill defined intent in NASA activities which lay between peaceful and military applications:

> Many primary NACA objectives, e.g. "the improvement of total performance of aerospace vehicles," were carried over as NASA objectives. These same objectives were shared by the military services with whom NACA and now NASA work closely to achieve.
>
> Objective 6 of the "Space Act" requires that NASA share its discoveries with all potential user agencies and identifies specifically those with military significance.
>
> Objective 8 stipulates that research facilities not be duplicated where sharing between agencies is possible. In other words there shall not be wind tunnels for peaceful research and duplicates for military research when sharing would eliminate the need.
>
> The "Space Act" refers to the advanced development of "aeronautical and space" vehicles, but in the definition of these terms, it is broadly defined to include missiles as well as all "related equipment, devices, components and parts."

Finally, the "Space Act" established an agency for peaceful pursuits, to enlarge upon technologies that at the time of the "Space Act" were supported by the military and developed to serve military goals.

However, since the actions of an agency are the final definitions of its policies, NASA's commitment to peaceful pursuits resulted in a number of policies sharply contrasting with the traditional military viewpoint. These are:

A policy of openness to the public and world press on all plans, launches and other activities the exception being to honor the Defense Department classification system.

An active pursuit of international relationships and joint ventures with other nations.

Strong programs to disseminate new advances in science and technology as well as to develop and assist domestic and international groups to become users of satellite weather and resource data.

NASA's close rapport with military aerospace activity, even its extensive use of military and ex-military personnel had no apparent impact on the image of peaceful intent projected by NASA. By the end of NASA's second decade of space activity, all but a handful of the nations of Earth had participated directly, in some fashion, with NASA in a space venture.

B. Conclusion: A Political Synopsis

The development of rocket powered missiles during World War II introduced the technical feasibility that man could reach space. World War II was followed by a continuing concern for national security spurred particularly by an unfriendly distrust of the Soviet Union. Thus the fire of World War II was replaced by a strongly competitive cold war during the 1950's. Under this pressure, the evolution of the military rocket advanced rapidly, and by the mid-1950's the scientific community considered some rocket missile boosters powerful enough to orbit a small scientific payload. However, such an enterprise had no military role at the time and suitable boosters were too costly and too vital to strategic defense for such purposes.

Satellite advocates in the scientific community, recognizing that scientific justification would not obtain a booster, approached the problem as a political one. They invented the International Geophysical Year. This august global scientific congress, with the objective of uncovering knowledge of the planet on a scale beyond the capacity of a single nation, would be a forum, adequate in political prestige, from which the satellite venture could be broached.

A satellite to measure and observe the Earth and the atmosphere from orbit was proposed by the delegates from the United States. The plan worked, and President Eisenhower annouced that such a satellite program would be a contribution of the United States to the I.G.Y.

Although the objectives for the satellite were purely academic, approval for the program had been won on political, not scientific grounds. The Eisenhower announcement gave it political status and marked the point at which the race into space became another objective in the cold war. Although this competitive aspect of the satellite program was recognized by the teams assigned to create the hardware for the program, it was not generally perceived by the Government, Congress, or the public until Russia placed its Sputnik into orbit.

The appearance of Sputnik came as a harsh disappointment to the American satellite teams, as well as to the equally aware among missile development personnel. Within hours of Sputnik's debut, the Administration became aware that it had erred in discounting the effect of a Russian victory in a race to orbit a clearly non-aggressive payload.

To Congress and the Nation, who for the most part were not really cognizant of the academic endeavors of the I.G.Y., of the American satellite program, or of the satellite competition, Sputnik came as an emotional shock, a stunning event with an unascertainable threat value.

Response in Congress was swift. The reaction of the United States to the Russian initiative was like a technological war without weapons. For seven years, funds were made available at the maximum rate they could be used. This rapid growth period has been called a substitute for war by some writers.

Early in this growth period, NASA was committed to a manned lunar landing, the initial phase of which was to test a one man space craft in Earth orbit (Project Mercury).

If funding patterns can be taken as a reflection of congressional mood, one must assume that the successful Mercury flights had a calming effect. By the time the Mercury flights were completed, unmanned missions had become almost routine. The United States had clearly demonstrated that it did not hold a subordinate position in space technology. In terms of funding, it appears that the completion of the initial manned orbital flights ended the urgency initially felt in Congress. NASA funding began a decade of rapid decline, finally leveling off in 1974 (in buying power) when it reached the amount received in 1962.

Congress, it seems, responded forcefully and immediately to what was perceived as a blow to national prestige and security when Sputnik appeared. While the events subsequent to the Mercury flights were a source of continuing awe to the entire world, Congress was not awed. Emphasis instead became centered on satellites which could demonstrate their worth in near term gains, and on projects to reduce space expenditures, such as the shuttle program.

The Winds of Star Wars

James E. Katz

(c) 1984 by Transaction, Inc.

In 1982, President Reagan proposed a space militarization program that could ultimately cost $18-27 billion. This declaration of intent, and the swirling controversy left in its wake, marks sharply renewed interest by the U.S. policy system in space programs, interest that had waned considerably, especially when contrasted to the period between Sputnik and the lunar landing (1957-1969). This renewed interest casts in bold relief the policy problems that have cropped up during a period of space policy neglect. Interest, however, is concentrated on antisatellite and space antiballistic missile warfare, rather than on across-the-board human use of outer space, even though technology has continued to advance in the latter area. This lag in policymaking presents problems, but also new opportunities, in the space policy field. During its foundation, national space policy was closely studied by the policy analysis community, but it has now been relegated to relative oblivion. Few serious social-scientific analyses of space policy have been published in recent years, and most of those that we do have are written by lawyers in international and space law or by military officers examining strategy and national security. The most recent policy study of NASA, for example, was published in 1975, despite the dramatic changes that have since occurred in its organization.

With occasional exceptions, as with President Reagan's "star wars" speech, space policy over the past fifteen years has been made on an incremental basis by divisions within the Office of Management and Budget (OMB), the Departments of State and Defense, and an isolated group of political appointees at NASA. Space enthusiasts in Congress are few in number, and their ardor is matched only by their ineffectualness. Yet, the post-Apollo disenchantment with the space program should not dampen the interests of policy analysts; this relative neglect of the space program, combined with technological change, has created fertile ground for policy analysis that could influence the social-scientific understanding of space policy and advance the processes involved in its formulation. Like the government, though, academic institutions also blow hot and cold on space policy. Not until the "star wars" speech did public policy analysts launch a flurry of activity.

In a recent speech commemorating NASA's twenty-fifth anniversary, Reagan suggested that it was time for NASA to get out of the way and let private enterprise astound the world with what it could accomplish in space applications. This suggestion, in keeping with other as-yet-unrealized suggestions by the administration for privatizing civil space activities, left NASA officials uncertain about their agency's long-term prospects. The bleak outlook is in marked contrast to NASA's spectacular rise to success culminating in the 1969 lunar landing. During its ascent, NASA was strongly supported by the public, the news media, Congress, and the president. This policy "movement" was successful in harnessing a technology to the betterment of national prestige. But NASA's rise has been followed by an equally rapid descent. As some policy analysts have suggested, when public support catapults a program to prominence, that program can just as quickly fall into a state of neglect, disappear altogether, or become the object of censure. After the Apollo mission, when NASA had no new meaningful goal to take its place, the agency suffered from problems of morale and the departure of superior personnel as tightening budgets and the lack of direction deflated organizational *esprit*. The temporary end of manned missions had a widely depressive effect.

Further along the chain of decline, the lack of public support and funding disrupted the network of university laboratories and training grants for space studies as well as the flow of newly trained space scientists. Aerospace contractors have also suffered, with many smaller firms having gone out of business; this in turn reduces the political support that can be marshaled from the private sector for a program in space.

NASA's supporters responded to this state of neglect by pursuing two major strategies. The first was the Apollo Applications Program and a manned orbiting laboratory, both of which met with public indifference, reduced as they were by budget-conscious presidential staffs and congressional leaders. This may illustrate a

Society
v. 21 Jan./Feb. 1984
p. 9 - 44

Catch 22 in the space policy situation: incremental policy produces modest programs, and these fail to attract the political support necessary for growth. The second strategy was to create imaginative and dramatic goals that would mobilize public and political support for an ambitious space program. In 1969, a White House–level task force, strongly influenced by NASA, recommended a gigantic program involving a moon base and manned Mars missions. Public skepticism about the legitimacy of space exploration and the cost of such a program kept the proposal from going anywhere.

President Nixon, nevertheless, did approve the space shuttle plan on a greatly reduced scale; otherwise, the lack of a significant project would have meant the imminent dissolution of the space program. These launchings have excited public support, but the program is lagging far behind schedule. Further, since the shuttle is absorbing money that could otherwise be spent on planetary and space research, it has become a target not only for NASA's critics but for disaffected groups within the agency. President Carter, although urged to fill the space policy vacuum by setting and supporting NASA goals, went no further than to issue a lackluster policy paper in 1978 which made no commitments. President Reagan's enthusiasm for civilian space programs has not been reflected in increased financial support; indeed, NASA budgets have been pared even more than under the Carter administration. Moreover, owing to the current administration's free enterprise ethos, much of the civilian space program periodically seems in danger of being turned over to private firms.

According to opinion polls, Americans believe that a superabundance of capital has already been invested in space exploration, especially in the apparently "wasted" effort of reaching the moon. Some critics have blamed NASA's public relations department for the agency's inability to generate popular support for the space program, not realizing that there are limits to the extent that public opinion can be manipulated by a single group. NASA's decline is the result of many external factors beyond the influence of a public relations department. The space program originated in the Cold War and was sustained by Cold War rationales. Concerns over national security and international competition placed the space issue beyond the manipulation of any one agency. Moreover, much of the early civilian space program was assisted by developments in military programs; the same knowledge needed to develop an ICBM force was also needed for the early space program. Today this kind of overlap is much reduced.

Though competition with the USSR over space exploration reached a low point in 1975 with the Apollo-Soyuz docking, some predict that technological progress and concern over Soviet aggressiveness will create a new climate of rivalry capable of motivating another ambitious space program. But it seems clear that the emphasis in such a U.S.-USSR competition will more likely be on military than on civilian programs.

NASA's current "identity crisis," owing to the lack of a meaningful program and political support, illustrates a kind of reverse technological obsolescence: that of a technology evolving beyond the political and social systems that manage it, instead of falling behind society's demands and uses for it. Technical capabilities in space have outpaced the ability of the nation to pay for them and of the political system to create and define purposes for them. In sum, the external competitive impetus for the original space program, the subsequent incrementally based policymaking system which precludes bold initiatives, and the changed focus for competition with the Soviets seem to have left NASA without a mobilizing purpose.

Satellites and Antisatellites

Space has become a central pivot of our national defense system. About 70 percent of U.S. military communications are transmitted by satellite. Satellites scrutinize ground activity, such as military installations, radar, and telecommunications; they monitor compliance with arms-limitation treaties and can make on-site inspections unnecessary. While the 1967 Outer Space Treaty banned weapons of mass destruction from space, other military activities have continued, with the focus shifting from "dropping atomic bombs" from satellites to combat between space vehicles, as in the current "star wars" scenario.

The reliance on satellites by both superpowers has made the ability to neutralize them or to launch attacks from them a crucial defense issue. President Reagan recently called for a bold effort to protect America through space-based weaponry—partly because of his fear of Soviet advances in space technology and partly because of American dependence on a vital and highly vulnerable satellite system. If U.S. guidance satellites are destroyed—and the threat to military satellites is no longer hypothetical—our 700 submarine-launched ballistic missiles become debilitated. The Soviet Union has been conducting hunter-killer tests for the past fifteen years and appears to have a quick-reaction killer-satellite system that can rendezvous with and destroy U.S. spacecraft in less than twenty-four hours. U.S. satellites have become this vulnerable as a result of policies and nonpolicies of the aerospace establishment. Because of the front-end cost effectiveness of satellites, many missions have been assigned to them without either calculating the cost of long-term vulnerability or creating alternative or redundant systems. Plans are under way to phase out the expendable booster, which will leave the United States with only three to five shuttles to get large objects (satellites) into outer space—shuttles, moreover, which are easy targets for antisatellites (ASATs). U.S. ASAT technology has been held back by the optimistic assumption that the Soviets will not take the next step in the space-war race, as well as by ever-present budgetary limitations.

The Soviets' pursuit of ASAT technology has now, however, motivated the United States to push its own program. The primary ASAT system being developed is a warhead-tipped missile fired from an F-15 operating at high altitude. The missile can neutralize a reconnaissance or other satellite in orbit, but it cannot intercept a Soviet ASAT (because the ASAT's orbit cannot be calculated precisely enough). Lasers, operating at the speed of light, may solve this problem; indeed, the Defense Department has spent about $1.5 billion to develop lasers that can destroy planes and some types of missiles. While the potential of the particle-beam weapon is largely unknown, proponents claim the Soviets are building just such an ASAT weapon system to knock out incoming ICBMs. The Defense Department is also trying to reduce the vulnerability of satellites by means of passive defense.

It is theorized that a "cold war" satellite arms race would result in an automated battlefield, involving only robots and remotely guided satellites, thus sparing earth from a nuclear Armageddon. Others argue that an initial conflict in space would be only the prelude to an expanded war on earth. So far, U.S. attempts to establish a treaty prohibiting ASAT weapons have failed. But it now seems that increased ASAT R&D by the Americans and the possibility that the United States might overtake the Soviet advantage in ASATs within five years have made the Soviets more receptive to such a treaty.

One disturbing aspect of the increasing ASAT activity is its potential effect on the fragile but vital deterrent created by each superpower's ability to obliterate the other. A sophisticated ASAT system, with its large military advantage, could destroy that balance, leading to a major escalation of the arms race and spreading it farther into outer space. The increase in ASAT testing is an alarming development not prohibited by international law or agreement, and it is obviously leading to a frantic technology race. A treaty banning all weapons from space, ASAT testing in particular, would seem justifiable. Yet, complete neutralization of space, as some have recommended, seems unfeasible. The technologies involved often serve peaceful uses, as well as military, and can be readily switched from one to the other. Furthermore, many military uses of space add to mutual deterrence capability, thus strengthening world security and stability.

As more nations attain launch capability, they too must be included in agreements designed to preserve space peace. Thus far, however, U.S.-Soviet negotiations have excluded all other countries. France has proposed an international satellite-monitoring agency; Italy has suggested a UN-sponsored multilateral discussion on disarmament and outer space. The nations of the world each have their own perceptions and fears about the space arms race, and these need to be taken into account when devising international space agreements.

Remote-sensing technology began in the 1800s when cameras in balloons photographed the earth by remote control. Today, the Landsat series and military satellites belonging to the United States and other countries are constantly scanning the globe, both on the visible and the invisible segments of the electromagnetic spectrum. These satellites can detect objects as small as 1 inch, temperature variations of .02 of a degree, trace amounts of minerals and chemicals, and a wide range of the electromagnetic spectrum (e.g., radioactivity, radar, and electronic communications). This technology has been compared to the microscope in its potential revolutionary impact. It permits the survey of pollution emissions, plant disease, building conditions, troop strength and deployments, armaments, ship and aircraft dispositions, and weapon or missile testing. Clearly, there are profound implications for environmental quality, allocation and conservation of natural resources, and surveying human and cultural resources.

This powerful tool has understandably engendered international contention; remote data-gathering presents economic, legal, political, and security threats. Satellites can provide economically useful data on such details as crop conditions, the location of ore deposits, and factory construction. Foreknowledge of agricultural conditions and thus of commodity prices, for instance, can improve a nation's economic viability in the world market when that nation is heavily dependent on sales of certain agricultural products. Satellite-generated data can also affect negotiations for a contract to explore or exploit a country's natural resource. Several nations, including Argentina and Brazil, assert that unrestricted sensing of territorial resources violates the sovereignty of their national wealth and resources, as protected by UN General Assembly resolutions. They define "national wealth" to include *information* about such wealth.

Freedom of Information?

The United States opposes this position, maintaining that the UN Charter, Article 19, advocates the right of all to "seek, receive and impart information and ideas through any media and regardless of frontiers." Washington has sought to reduce opposition to its practice of comprehensive surveillance by giving any individual, entity, or state—including those with differing political philosophies, such as the Soviet Union and the People's Republic of China—complete access to all data gathered by the Landsat series upon payment of a nominal fee. But the U.S. position is weakened by numerous domestic and international treaties and court decisions that give nations the right to control or prohibit photography in their airspace or into their territory. No definition of "airspace," however, is universally accepted. Some nations would extend the term to include the area of Landsat orbits.

There is also opposition to the use of satellite-generated data within the United States. Although U.S. courts have consistently maintained that information is a protected property right, the government consistently ex-

propriates this nonphysical, but still exchangeable, form of property through satellite sensing. No one has litigated on this particular issue, but a legal proceeding has been initiated on the basis of evidence gathered by satellites. Water-borne pollution detected by Landsat has resulted in a court battle over violation of pollution laws. The potential for future legal cases related to satellite-generated data encompasses zoning laws, personal privacy, criminal conduct, and industrial espionage. The legal and constitutional issues of privacy, evidence, and data gathering that result from remote sensing have only begun to be studied. Looming on the horizon are satellite threats to civil liberties. This is not so farfetched as it might seem; during the Vietnam War, satellites were used to monitor antiwar demonstrations.

Many nations tightly control even innocuous information, perceiving its discovery as a needless threat to their stability and security. Other countries' sensitivity to military data gathering can be explained by the fact that satellites can read such details as license plates and uniform insignia. While nations attempt to baffle satellite reconnaissance with various disguise techniques, remote sensing is still the cornerstone upon which strategic arms limitation rests, for it permits the monitoring of treaty compliance.

The use of geostationary orbits is another controversial area. Such orbits (corridors, at about 35,800 kilometers over the earth's equator, where satellites can be placed to maintain a constant position relative to earth) make ideal parking places for satellites in constant contact with a particular ground station. The geostationary orbits over the United States and Canada are already congested, and with increasing demand for telecommunications, broadcasting, meterological, and (possibly) power transmissions, competition for them is intensifying even more.

The United States argues that space can be freely used by all nations without discrimination, if the purpose is for the "benefit and in the interests" of all countries, but it does not wish to limit the definition of "benefit." Eight equatorial countries (Colombia, Brazil, Congo, Ecuador, Indonesia, Kenya, Uganda, and Zaire) have claimed the segment of the geostationary orbit above their national territory as their sovereign domain, formalizing this claim in the Bogotá Declaration. The declaration, then, seems to contravene the 1967 Outer Space Treaty (upholding free exploration and use of outer space) by making foreign occupation of a nation's geostationary segment tantamount to appropriation. The Bogotá signatories defend their position on the basis of equity, rather than international law. They maintain that, under current practice, only the least desirable locations and frequencies will be left for those countries with the most modest financial and technological resources, and that the 1967 treaty, if applied to geostationary orbits, does not carry out its drafters' intention, which was that space development benefit all nations in order to achieve a more just international order.

The exploitation of space has not followed any rationally developed plan but has evolved gradually. No nation has asked permission before orbiting a satellite, and no official protests were heard until Colombia's in 1975. Thus, a commercial satellite operator in the United States has recently placed one of its satellites in geostationary orbit several years before its service will be needed in order to prevent someone else from taking the space. In 1979, Western Hemisphere nations met to seek equitable distribution of the five available satellite spaces, only to discover that the United States was already occupying four of them.

No specific plan effectively addresses the current dispute, which is now in limbo because the equatorial nations cannot remove or interfere with already stationed satellites. If they should attempt to enforce their claims, action against terrestrial targets (e.g., an embargo or property seizure) is a possibility. The United States should develop policy for dealing with such contingencies.

Added to the controversy over positioning of satellites is a controversy over communications per se. For political, cultural, and economic reasons, some countries want to monitor programs broadcast into citizens' homes, including "cultural" programming that may be distasteful, contain unwelcome information, or invite invidious comparison. Even "open societies" may resist direct broadcasting by satellite, fearing that their national culture might be submerged.

The United States and some other nations maintain that the flow of information should be subject to minimal regulation, such as prior notification and consultation, but not to regulation that would inhibit future technological development and the free exchange of ideas and information. The USSR advocates prior consent, controlled program content, and the prevention of illegal broadcasts. Argentina adds even more restrictions, including a right of reply as well as proscriptions against any telecommunication that threatens the security of the state or family or that "impairs the rights of families or individuals, or is contrary to public law or morality."

Three policy issues are at sake in the direct-broadcasting-from-satellites issue: the free flow of information; recognition of the value of cultural diversity; and a nation's right to determine the character of the television services available to its people. The resolution of one can mean further controversy and bitterness over the other two.

Exploiting Space

Less-developed countries want to be able to share in nonterrestrial resources, which they feel are the common heritage of all mankind. The technologically advanced countries argue that this attitude would destroy the commercial incentive to exploit the resources of space. Debate over international policies for such space enterprises as moon or asteroid mining centers around the same concerns as these which dominated the Law of the Sea negotiations on sea-floor mining.

Argentina was the first country to propose a treaty on the use of the moon. That treaty—emphasizing exclusively peaceful uses of space, mandating that any resource development promote higher living standards and socioeconomic progress on earth (especially in developing countries), and prohibiting weapons of mass destruction, weapons tests, military installations, and maneuvers—was at first ignored. The general feeling was that the 1967 Outer Space Treaty dealt adequately with the moon and other celestial bodies. But over time the proposed treaty gathered support and was finally passed by the UN General Assembly. Although the United States signed the treaty, during the Carter administration, the Senate refused to ratify it and the Reagan administration quickly withdrew it from further Senate consideration.

The treaty is now moribund. Natural resources and the international regime necessary to regulate their exploitation are the main areas of disagreement. The United States favors development and rational management of the moon's natural resources, expansion of opportunities for the exploitation and use of those resources, and equitable sharing of benefits derived from those resources—all of which are included in the treaty—but the treaty does not define "equitable sharing of benefits."

Some fear that the international-authority model devised to control seabed mining (and which effectively prevents it) will be used to control the exploitation of celestial resources. Some U.S. policy communities do not believe that an international regime would blunt lunar exploitation as the sea authority has marine mining. They further argue that, in any event, such an international regime is necessary only when exploitation of space resources becomes feasible—which may be years away, or never. In the meantime, arrangements can be made for rational experimentation with various organizational approaches in order to develop effective procedures. While the United States feels it has committed itself only to working on the establishment of an international regime, not necessarily to participating in one, some legal authorities say that the treaty makes submission to an international regime a prerequisite to resource exploitation.

Opponents of the treaty believe that it will prevent space settlement and exploration and that it will slow, if not halt, both the development of space technology and the exploitation of vital resources that would elevate world living standards. Some even believe that it constitutes a fundamental abrogation of civil rights. One section of the treaty allows any government to inspect a space station in orbit around any celestial body except earth; a government would not need permission to board and search such a space station. The U.S. Congress believes the treaty may have the same effect as the Law of the Sea; i.e., through international sharing-and-control provisions, extinguish corporate interest in exploitation.

The growth in space technology has prompted a search for institutional arrangements which can guide space exploration and exploitation. The numerous conflicts described above suggest that the current international infrastructure is inadequate for outer space. Because technology has developed more rapidly than social institutions, nations are having a difficult time agreeing about the fair and efficient allocation of resources. Thus far, there have been two basic approaches to the problem. One, the "national authority" approach, involves nation-states assuming responsibility and authority for the allocation of resources and, where possible, sovereign control of those resources. The other, "functional eclecticism," calls for the incremental growth of international authority and results in an ungainly mixture giving specialized functions (e.g., telecommunications) to particular institutions (e.g., INTELSAT) while leaving complex, but more general, issues (e.g., allocation of geosynchronous satellite "parking places") unresolved.

One possible institutional solution would be to develop a powerful "outer space projects agency" with an international membership. Such an agency could gradually internationalize capabilities for gathering and assessing information derived from remote sensing and about outer space, leading to a fuller sharing of such information. It could also push for intensive international consultations to resolve contending interests and to develop a wider range of policy choices for the international community. Finally, a space projects agency might limit nationally oriented (i.e., self-interested) activity in outer space by enforcing binding reciprocal obligations that would lead to a mutual accountability network. That such an organization will ever be formed, however, is decidedly remote.

This overview of emerging space policy problems has intentionally shifted across many different areas to show the abundance of issues of concern to policy analysts. This survey reveals a rich quarry for those interested in bureaucratic politics, decisionmaking models, organizational processes in constrained environments, links between public opinion and public policy, links between international and domestic policy, societal development, and even futurology. Moreover, the general neglect of the space policy area has reduced the cacophony of "common sense" rhetoric from politicians and ideologues, leaving a zone relatively free of politics and entrenched interests into which social scientists can venture, armed only with their analyses and theories. But this zone will not long remain tranquil. The "winds of star wars" have begun to blow. As their velocity increases, social scientists will have less and less opportunity to make a difference in policy formulation. □

James E. Katz, now with the Lyndon Baines Johnson School of Public Affairs at the University of Texas-Austin, previously taught in the Department of Sociology at the George Mason University, Fairfax, Virginia. He is the author of Nuclear Energy in Developing Countries: An Analysis of Decisionmaking.

Military Uses and Implications of Space

Thomas Blau and Daniel Gouré

Today, U.S. strategic policy remains committed to deterring nuclear war through the threat of punitive retaliation against potential attack. Yet, in light of the enormous nuclear arsenals of both the United States and the Soviet Union, this strategy increasingly places the United States at risk and reduces the credibility of the retaliatory threat. Concerns for escalation control, worried allies, and growing Soviet third-strike retaliatory capabilities have limited the use of strategic power except under the most extreme circumstances (e.g., defense of the United States against a Soviet attack). Long-standing U.S. security guarantees to its allies, for example, increasingly appear incredible both to them and to Americans.

Despite arms control and other areas of coincidental interest, relations between the United States and the USSR are still defined mainly by the shape of the military balance. Whereas the active use of military force for political purposes and in defense of national interests shows no sign of decreasing throughout the world, avoidance of direct conflict, particularly nuclear war, will continue to be central to superpower relations and to the policies of the two blocs. However, superpower nuclear-war avoidance does not negate the political utility of military capabilities. Thus, a military "balance" that both favors the Soviet Union and inhibits U.S. flexibility and initiative conflicts with the global character of U.S. national interests.

It is, therefore, not surprising that the United States is experiencing profound uncertainty over the character and purposes of its military power. Driving the uncertainty is a growing sense of national and personal insecurity over the inability of the United States, either alone or with other countries, to achieve a stable strategic balance. Such a balance was pursued in the 1970s when the United States acquiesced in the Soviet drive for strategic equality. At that point, the Soviets were to have accepted a roughly equal deterrence and to have joined the United States in a search for additional stability in the superpower relationship. This has not happened.

Both the Reagan administration and the anti-nuclear-freeze movement see the present situation as dangerous and potentially unstable. The main responses to this situation have tended, at least lately, to be either increasingly complex and hard to understand (such as the late "dense pack" plan for basing new U.S. intercontinental ballistic missiles) or drastically simple given real-world problems (such as unilateral disarmament). At the very least, then, profound political issues are raised by changing the U.S. strategic deterrent and its underlying policies.

The U.S. deterrent, in many key respects unchanged since the mid-1960s, now faces vastly more threatening forces on the other side. Until recently, suggestions for restructuring or upgrading U.S. strategic forces focused almost completely on strategic offensive forces. In part, this reflected the dominance of offensive thinking and of coercive deterrence embodied in the doctrine of mutual assured destruction (MAD), which viewed the notion of defense as ineffective if not actually destabilizing. This view was codified in the 1972 Anti-Ballistic Missile (ABM) Treaty, the centerpiece of the Strategic Arms Limitation Talks (SALT). This treaty not only banned existing strategic defensive systems but also effectively prohibited deployment of future, more effective ones.

U.S. strategic forces have been shaped by marginal improvements to existing systems and by the effort to draw the Soviets into arms control measures. There has not been much effort to respond to Soviet buildups with fundamentally new or different U.S. capabilities or to address the broad, long-term viability of the U.S. strategic deterrent, now threatened by hard-target, counterforce goals in Soviet buildups. The problem with counterforce is that it implies a destabilizing interest in a first-strike.

For some, such as key figures in the Reagan administration who did not believe that deterrence was automatic and inevitable in the new strategic imbalance, there was a need to negate additional Soviet advantage, to close what the president called the "window of vulnerability."

Simply adding to U.S. offensive forces, however would at some point increase the frustration and the moral question of peacekeeping through the threat of mass annihilation.

It is understandable, then, that the Reagan administration would try to rethink U.S. strategy. The president's "star wars" speech on March 23, 1983, may someday be seen as a milestone in that effort. The administration is now studying the potential military applications of outer space, giving special attention to the possible deployment of strategic defenses in space. The press reports that these studies will recommend to the president an accelerated five-year research and-development program costing $18-27 billion, possibly to deploy strategic defensive weapons in space as early as the year 2000.

Such a move would shift the military, political, and moral basis of deterrence. There is, therefore, a clear need to understand the military uses of space as well as the political and strategic implications of deploying weapons in space. More broadly, the idea of building defenses against nuclear weapons, while not new, again raises old issues: What are the United States' national security objectives? How should U.S. forces be configured and employed in the attainment of those objectives? How stable will such a future world be?

While the Reagan administration emphasizes the primacy of deterring the USSR, others, such as Herbert Scoville, Richard Garwing, and Paul Warnke, see primacy in the arms control negotiation process. They tend to reject options that involve newer, larger, or more elaborate U.S. defense planning or that mitigate U.S. vulnerability in the balance of terror.

The American interest lies in the increasingly questionable strategic balance, the current use of space for military applications, and the considerable lead taken by the Soviets to use space for military purposes. Outer space is now critical to military command, control, and communications (C^3), warning, reconnaissance, and arms control verification, among other functions. If one side's satellites devoted to these tasks were destroyed, it could be rendered "blind, deaf, and mute." It is, therefore, especially sobering that the Soviets have conducted a score of satellite-killer (ASAT) tests; the United States, none.

It is conceivable that the USSR may be able to combine military leadership both in advanced space applications and across the range of traditional capabilities, thus producing grave *political* problems, at least. Space forces, for example, might offer an aggressor the chance to destroy the critical space-based warning and C^3 assets of the defender. For the defender (i.e., the United States), however, space may be critical to frustrating any potential Soviet planning for central war. Even a limited ability to defend the United States or its military assets could provide disproportionately large deterrent benefits, if only by complicating all the decisions made by a would-be aggressor in planning his attack. Because of the enormous burden of calculated coordination that a nuclear attacker faces, confidence reduction—especially in the early moments, when the attacker must deal with warning and C^3 assets—may well critically blunt the edge of a potential first-strike and thereby deter it.

Amendment Required

If space applications can undermine the utility of the potential aggressor's superior forces, then popular perspectives on space require amendment. Those notions are, *first*, that space is an arena for peaceful scientific and humanistic development, in which military activity is neither desirable nor feasible and is subject to being banned in any event; *second*, that space can only passively supplement routine, terrestrial political-military concerns (e.g., arms control verification); and, *third*, that in the extreme, space can be no more than an arena of localized military operations between ASATs, target satellites, and perhaps defensive satellites (DSATs).

To assume that space is militarily useless can turn out to be a "self-fulfilling contradiction" if someone else should establish a visible breakthrough. The impact then may be all the greater because of the gulf between the initial passive, skeptical view of the military use of space and the results exploited by the other side. Surprise will result in shock (a central concept in Soviet military planning).

The military uses of space occupy three levels, which correspond to the current, medium, and long terms:

- There is an immediate need to support earth-based activities and military forces from space, including early warning of attack, C^3, navigation, intelligence gathering, weather monitoring, and even direct U.S.-Soviet communications via the "hotline." Most of these functions relate not to nuclear war but to the day-to-day, peacetime operation of U.S. military forces, the verification of arms control agreements, and the surveillance of global military activities.
- The prospect of combat in space is raised by the impending deployment of workable antisatellite weapons, which will threaten many current support satellites. This is a medium-term issue.
- Space might also be utilized to defend the United States and its allies from the growing threat posed by Soviet strategic and theater-nuclear forces. In the long term—after the year 2000?—a space-based defense against missile attack is possible.

The United States, its allies, and the Soviet Union are now critically dependent on space for the performance of a large number of national-security-related functions. Space-based sensor systems provide early warning of ballistic missile attacks. To provide global strategic and tactical communications, the United States maintains the Defense Satellite Communications System (DSCS), the Fleet and Air Force Satellite Communications Systems (FLATSATCOM and AFSATCOM, respectively), the NATO Communications Satellite System, and the Satel-

lite Data System (SDS). The Soviet Molniya system provides Moscow with a similar capability.

Both the United States and the Soviet Union depend on a variety of satellite-based sensors for purposes of surveillance, reconnaissance, and strategic targeting. Such systems employ a wide variety of sensing systems, including photographic, infrared, radar, and electromagnetic. While the United States is believed to be ahead in high-resolution photographic and image-sensing systems, the Soviet Union possesses several unique systems—in particular, its radar and electronic oceans-surveillance systems (ROARSAT and EORSAT, respectively). It has recently been reported that the Soviet ROARSAT system is capable of providing "real-time targeting" of U.S. warships for Soviet cruise missiles. This means that the Soviets can engage U.S. ships at extremely long range (up to 300 km.), outside their air-defense envelope and without requiring a nearby ship or plane to provide in-flight target tracking.

In addition, there are meteorological and navigational systems which provide information necessary both for accurate strategic targeting and for the operation of conventional and naval forces. The U.S. NAVSTAR Global Positioning System, based on a planned constellation of twenty-four satellites (eight are now deployed), will provide accurate (within 30 m.) time-of-arrival for position location anywhere on earth. The Soviets intend to deploy a similar system.

Satellite surveillance systems help maintain superpower peace, verify arms control agreements, and guard against nuclear proliferation. In 1978, President Carter noted that "national technical means of verification," central to enforcement of the strategic arms control agreements, relied heavily upon satellite systems. Their ability to provide reliable data on a potential adversary's state of military preparedness has allowed powers to limit their own military plans accordingly.

Central to the further exploitation of space, whether for military or civil purposes, has been the ability to place and to maintain men and machines in space. The U.S. space shuttle makes it possible to place 65,000 pounds of payload in low earth orbit (1,000 mi. above earth). This will enable the United States to orbit larger, more complex satellites. Additionally, the shuttle could be used to support construction of a permanent station in space. The Soviet Union appears to be on the verge of creating just such a permanent station.

Space-based systems have for many years served as a force multiplier, enhancing the effectiveness of more conventional military force. However, it is the likely deployment of active weapons, as distinct from the current passive systems in space, that promises to alter radically the nature of war and military planning.

Currently, there are no weapons in space, and their future deployment may be limited by a series of treaties. The 1967 Outer Space Treaty bans all nuclear weapons in space, on the moon, and on other celestial bodies. The 1972 ABM treaty also bans the deployment in space of systems capable of attacking ballistic missiles. The United Nations has proclaimed space to be a "zone of peace." No treaty, though, prohibits the passage of nuclear-armed missiles through space. Nor does any treaty directly prohibit the deployment of ground-based antisatellite weapon systems, such as those currently possessed by the USSR and under development by the United States. While some have argued that international law views space as a place where war is banned, this zone is increasingly indispensable to terrestrial military planning and force posturing.

While some argue that international law views space as a zone where war is banned, this zone is increasingly indispensable to terrestrial military planning and force posturing.

U.S. satellites are increasingly threatened by the Soviet ASAT system, the only one now operational. It was recently tested as part of a nationwide military exercise involving nuclear strikes on U.S. military forces as well as employment of the Soviet ballistic missile defense (BMD) system against U.S. forces. The Soviet ASAT is a large conventional or nuclear-armed satellite launched by a version of the SS-9 ICBM into a co-orbital intercept with the target satellite. The present-generation Soviet system would be effective only against satellites in low earth orbit, although use of a larger booster could allow the system, particularly if armed with a nuclear warhead, to attack U.S. communications and early-warning systems in geosynchronous orbit (22,500 mi.) by means of electromagnetic pulse. Such a capability has long been sought by the Soviet Union in its pursuit of the means for successful nuclear-warfighting.

The United States is taking a number of steps to improve the survivability of its satellite systems against attacks in space or on the ground. An announced $18-billion satellite-survivability program will provide protection for vulnerable earth stations and communications facilities as well as for the satellites themselves. Some systems, such as defense communications satellites, have "silent spares" already in orbit which can be used to replace operational systems. Other avenues of protection include the development of a rapid-reconstitution capability, hardening of satellites against shock or nuclear effects, and enhanced ability to maneuver out of harm's way. In addition, the United States is currently developing a comprehensive threat-management and

surveillance system to track all U.S. satellites and to warn of an impending attack.

Moreover, the United States has sought to develop a countervailing threat to Soviet ASATs. The U.S. system will consist of a miniature homing vehicle (MHV) mounted on a two-stage rocket and carried on an F-15 or similar aircraft. Launched in the air, it will home in on Soviet satellites and destroy them by direct impact. Although the U.S. system will not reach the high altitudes of the larger Soviet rockets, its flexible launch mode will permit its use against low-orbit satellites from virtually any spot on the globe.

The growth in the military and civil uses of space has created a gray area of systems and functions having both military and nonmilitary application. The U.S. space shuttle will transport military as well as civilian payloads, and the Soviets have repeatedly insisted that the shuttle can be used to "capture" satellites. Space stations can likewise be used for a variety of purposes. The Soviet Salyut space station may well be intended as a military observation post and a base for Soviet ASAT weapons.

These early-generation space systems are the forerunners of a broad array of potential support and active military capabilities in space. Advanced infrared technology and mosaic-array sensors may provide the basis for detecting ballistic as well as air-breathing threats from space. One such system, currently being tested under the name Teal Ruby, may serve as the space-based sensor component of a large air-defense capability. Advanced concepts in BMD include use of a mosaic-array sensor overlay which, when launched into the path of an incoming ballistic missile attack, discriminates targets for a ground-based anti-ballistic-missile defense. Other proposed U.S. systems include laser satellites for communicating with submerged submarines; radar satellites, similar to one now operated by the Soviet Union, for ocean surveillance; and improved photographic and sensor satellites for intelligence gathering, submarine tracking, and arms control verification.

Breaking Out of the Future

Even more revolutionary is the prospect of placing BMD as well as ASAT weapons in space. If a defensive system could be put into space, ballistic missiles might be intercepted in the boost phase, prior to separation of the warheads from the missile itself, thus simplifying the defensive problem.

In 1972, it was argued that banning BMD made sense because the technology was rather primitive and unproven and because the attacker could always develop means to counter any defense. Since both sides were believed to be focusing on deterrence, by means of a capability for assured destruction of soft targets (i.e., cities), additional weapons would serve no purpose; they would be "overkill." Defenses for cities, it was argued, would have to be 100 percent effective in order to preclude catastrophic damage, so no defense appeared feasible. However, the possibility of placing a BMD system in space, either alone or in concert with other defenses in a layered effect, invites reexamination of that argument, especially if one's goal is less ambitious than guaranteeing the safety of cities; namely, to preserve some of one's ICBMs in the event of a first-strike.

Ballistic missile defense, in or out of space, now draws interest for a number of reasons. First, even a marginally effective ability to increase an aggressor's uncertainty by complicating his military planning would buttress deterrence. Second, such defenses reduce the potential for catastrophe from an accidental launch, or from a small or third-party nuclear attack. If it could defend itself against such attacks, the United States would not have to respond to limited attacks by retaliation against the USSR. Also, strategic defenses against missiles reduce the plausibility of preemption and cheap victory—again, increasing stability.

The U.S. government is now spending almost $500 million on the development of directed-energy weapons, and soon this figure may well climb to several billion dollars.

Strategic defenses may make sense precisely because they can provide a plausible middle ground between unilateral disarmament, on the one hand, and a continual buildup of offensive forces, on the other. BMD could be the foundation for a panoply of national defense capabilities, including cruise missiles and submarine-launched missiles for a measure of defense against jet aircraft. A defensive posture could provide a practical method of reducing both the likelihood and the consequences of war.

A wide range of technologies are currently being investigated for use in space. Some involve the use of near-term technology in the form of MHVs, pellet charges, or other devices intended to be launched on warning of attack and designed to use the kinetic energy from direct impact with the target. One proposal that has received public attention is the High Frontier concept, whereby existing technologies would be used to deploy a fleet of more than 450 satellites armed with multiple homing rockets for a global BMD. This system is distinctive in that it combines available technology with space-basing. High Frontier advocates insist that their system can be deployed within a few years and at relatively low cost. Their critics disagree sharply.

Potentially far more dramatic would be the deployment of directed-energy weapons—lasers, charged particle beams, and X rays—which can pass easily through empty space. A congressional study has suggested that

"the potential of high-energy laser technology for altering the strategic balance between the U.S. and the USSR is presently unique." Likewise, a report by the General Accounting Office has recommended that the Defense Department speed up the development and deployment of "a constellation of laser battle stations in space" in order to blunt a Soviet strategic attack. Orbiting in space, a directed-energy BMD system could blunt the cutting edge of a Soviet attack as well as defend U.S. satellites from Soviet ASATs.

The United States may be able to deploy a rather simple, low-power laser weapon within ten years. Such a system probably would not be able to serve in a ballistic missile defense role but could defend U.S. satellites against ASAT attack. More-sophisticated systems could be developed within fifteen or twenty years—able to attack not only ballistic missiles but aircraft and even low-flying cruise missiles. One proposal under study is to deploy X-ray lasers powered by a nuclear explosion. In the event of an attack such satellites would detonate themselves, sending out beams of X rays at approaching missiles. Unlike laser satellites, such a system would not need to carry large fuel supplies.

The potential multiple applications of directed-energy technologies make them especially interesting. Such systems could also help protect U.S. warships against attacks from aircraft or cruise missiles and could provide national air defense. Clearly, positioning such weapons in space would give them a range and coverage capability denied to any ground-based weapon.

No one has yet tried to deploy an array of armed satellites. Merely procuring and launching them would be a very costly and complicated enterprise. Estimates of the costs go as high as $300 billion, the likely figure being in the $50-100 billion range. Additionally, directed-energy weapons require extremely high pointing-accuracy, exact target trackers, and very high power output if they are to be used against ballistic missiles. Such technologies are only in the development stage. Currently, the U.S. government is spending almost $500 million on the development of directed-energy weapons, and if supporters have their way this figure will soon climb to several billion dollars.

The "awesome" potential (as a U.S. government study put it) of new space-based technologies is prompting a gradual readjustment of military doctrine and strategy with respect to space-based systems. In September 1982, the Air Force created a Space Command to exercise consolidated control over the vast array of Air Force space programs. Much as the development of the Strategic Air Command presaged a fundamental shift in U.S. strategy and doctrine, so the advent of Space Command suggests an attempt to coordinate U.S. operations in space.

The real innovation of President Reagan's March 1983 "star wars" speech lies not in his suggestion that a new ballistic missile defense might successfully repel attack, but in his call to "break out of a future that relies solely upon offensive retaliation for our security." The core of the president's vision was to ask, "What if free people could live secure in the knowledge that their security did not rest upon the threat of instant U.S. retaliation to deter a Soviet attack; that we could intercept and destroy strategic ballistic missiles before they could reach our own soil or that of our allies?" Perhaps, then, the determining factor in America's military exploitation of space will be a change in U.S. strategic policy and its objectives—most notably, a movement away from strategies of mutual assured destruction (SALT, Carter), nuclear-warfighting (early Reagan), and unilateral disarmament and toward survivability.

A minimum aim of U.S. strategy under pressure from the comprehensive Soviet buildup, then, should be to buttress the strategic deterrent by increasing the uncertainty of Soviet planners about the probable success—by any standard—of an attack on the United States. Conversely, the Soviet aim implied by ASAT experiments and by Moscow's drive for superiority is to increase their certainty of success should they choose to attack. Ironically, supporters of MAD would oppose U.S. attempts to lower U.S. vulnerabilities—arguing that this might increase the likelihood of nuclear war.

Is there a chance of avoiding military competition in space by negotiating a demilitarization there? The first step toward this goal could be a treaty banning or freezing the development and deployment of ASATs that threaten critical military-support satellites. Further agreements might specify permitted and prohibited military functions in space. Problems, such as the degree of Soviet interest, compliance, and good faith in such an agreement, however, would continue to be very serious.

The opportunities for both military advantage and mutual stability arising from the exploitation of space suggest that the possibility of maintaining space as a "demilitarized" area has already been denied. The threat of hostile action against key U.S. satellite support systems is potentially great enough to mandate a response, if only to maintain the currently precarious strategic balance. More important, strategic defenses become increasingly seductive in light of the Soviet capability to employ force and to neutralize U.S. reaction at almost every potential level of conflict. Only strategic defenses seem to offer the prospect of moving away from the political and strategic precipice represented by assured destruction. Only by deploying defensive capabilities, moreover, can the United States begin to ensure its own survival in a nuclear conflict. Space is a promising medium for such a deployment.□

Thomas Blau, a partner at Decision Directions, has been a consultant on outer space issues with U.S. government agencies.

Daniel Goure has been a consultant to the U.S. Department of Defense on space policy. He has written extensively on strategic defense, Soviet military affairs, and weapons in space.

America's International Space Activities

Marcia S. Smith

The U.S. space program has been international in character since its inception. The 1958 National Aeronautics and Space Act, which created NASA, states that space activities of the United States shall be conducted so as to contribute materially to cooperation with other nations, both in work done pursuant to the act and in the peaceful application of the results of such activities. Directives by President Carter in 1978 and President Reagan in 1982 reiterated this policy, although the Reagan directive added that international space activities shall be pursued if they provide "scientific, political, economic, and national security benefits."

The Reagan language illustrates the many facets of international space cooperation. Initially, the international component of NASA's program was pursued for two reasons: first, because of a genuine desire to involve other countries in exploring the new frontier of space; second, because NASA required worldwide tracking locations and wanted to generate a climate in which other countries would be predisposed to allow tracking sites on their territory. Later, as national budgets became more constrained, the economic benefits of cooperation also became important. Programs that were too expensive for the NASA budget could still be pursued if another country or group of countries were willing to provide some of the instruments, or even entire spacecraft. Similarly, by offering free launch and tracking and data acquisition services, U.S. scientists might be invited to fly instruments on a foreign satillite or at least to receive data. More recently, under the Reagan administration, national security has become a watchword in virtually all technology areas, and space is no exception.

There are many different types of cooperative programs, primarily sponsored by NASA, ranging from the exchange of scientists to joint development of spacecraft. One of the largest categories of cooperation has to do with the reception of data gathered by U.S. satellites, especially meteorological and remote-sensing satellites. The NASA-developed automatic picture transmission (APT) station for receiving data from polar-orbiting weather satellites is in common use throughout the world, so much so that agreements are no longer signed for their use. The equipment is available through several international outlets.

The direct reception of land remote-sensing data from Landsat satellites, however, does require signed agreements. At the end of 1982, when this article was drafted, eleven foreign Landsat ground stations were in operation at the following locations: Argentina, Australia, Brazil, Canada (two stations), India, Italy (owned by the European Space Agency, ESA), Japan, South Africa, Sweden (owned by ESA), and Thailand. In addition, Indonesia and China have signed agreements to build ground stations, and several other countries have indicated interest. (Three agreements, with Chile, Iran, and Zaire, have lapsed.) Each country pays an annual access fee ($600,000 beginning in October 1982) and agrees to provide the United States with any data it needs. Originally, NASA was responsible for these agreements, but with the transfer of the operational Landsat program to the Department of Commerce's National Oceanic and Atmospheric Administration (NOAA), the latter agency has taken over these activities.

NASA sponsored a program for assisting countries in interpreting remote-sensing data from Landsat 1 and 2

and the Skylab EREP (Earth Resources Experiment Package) program. Approximately fifty countries participated, with NASA selecting individual experiments according to scientific merit. No exchange of funds was involved. Although the NASA program has been terminated, the Agency for International Development (AID) sponsors seminars throughout the world to demonstrate the value of remote-sensing data and has established three regional remote-sensing centers (in Thailand, Kenya, and Upper Volta).

A third category of cooperation concerns the launch of satellites. There are two types of agreements, cooperative and reimbursable. In a cooperative launch, there is no exchange of money; instead, data and services are exchanged. For example, the United States might launch a satellite in which the payload has been developed jointly, or a foreign country may provide the entire spacecraft; in return, U.S. scientists are given access to the data. In a reimbursable launch, a country pays to have the United States launch a satellite (usually for communications). Through the end of 1982, there had been twenty-nine cooperative launches and thirty-eight reimbursable launches (not including thirty-three for the International Telecommunications Satellite Organization, INTELSAT). Italy has also launched several U.S. satellites, using U.S. launch vehicles, from its San Marco platform off the coast of Kenya.

The programs designated "cooperative," rather than those that are "reimbursable," probably represent what most commonly comes to mind when discussing cooperative space activities in which both sides contribute to the development of a space program and the analysis of the data. Throughout the history of the space program, most such missions have involved U.S. spacecraft on which the United States has offered foreign scientists the opportunity to fly experiments; in a few cases, though, the other country has provided the entire spacecraft for launch by the United States (e.g., the Helios spacecraft built by Germany for solar studies). Also, the Soviet Union has launched a few spacecraft that carried U.S. experiments. With the attainment of independent launch capabilities by other countries (notably the European Space Agency), the situation is now reversing to some extent, and opportunities exist for U.S. scientists to fly experiments on foreign satellites at a time when the U.S. space-science program suffers from budget constraints. U.S. international space activities are extensive and cannot be treated comprehensively here. A few examples of cooperative endeavors, both successful and not so successful, are provided below.

Cooperation with the Soviets

The most visible example of international cooperation is the 1975 Apollo-Soyuz Test Project (ASTP) with the Soviet Union. The United States launched a three-man crew in an Apollo spacecraft to dock with a two-man crew in a Soviet Soyuz. The five men exchanged pleasantries and gifts and conducted several scientific experiments in the two days that the ships were docked together. After undocking, the two ships conducted docking and eclipse experiments for two days. The Soyuz then returned to earth while the Apollo remained in orbit for three more days to conduct additional scientific experiments.

The ASTP mission was notable primarily because it involved cooperation between two traditional space competitors. There had been little cooperation between the United States and the Soviet Union through the 1960s, although agreements had been signed in 1962 and 1965. In 1969, NASA initiated talks for new cooperation which led to a 1970 agreement to study the possibility of a joint manned mission. In 1972, an accord was signed by President Nixon and Soviet Chairman of the Council of Ministers Kosygin which led to ASTP.

The ASTP mission was criticized as an expensive method of demonstrating the warming of relations between the two countries. Some feared, also, that the United States would be giving away advanced space technology to the Soviets. Seven years later, however, it is difficult to point to a single example of new space technology being used by the Soviets that might have come from their experience with ASTP (except for the remodeling of the Soviet mission-control center to resemble the one at NASA's Johnson Space Center). While U.S. engineers did not take home invaluable technical expertise either, at least some new information was gained about the secretive Soviet space program. U.S. astronauts and support personnel were allowed to visit the Soviet launch facility at Tyuratam, and were able to study the Soyuz spacecraft (later noting that it was closer to America's 1965-era Gemini spacecraft than to an Apollo). The West also obtained details of a 1971 Soviet space mission in which the three-man crew died during reentry—information that might not have become available without ASTP.

Another cooperative agreement, signed in 1977, included the suggestion that a mission involving the U.S. space shuttle and the Soviet Salyut space station be pursued. In addition, the Soviets offered to fly U.S. experiments on several of their biological satellites. The first such mission had been successfully accomplished in 1975, and three more were envisioned in the 1977 agreement (two were flown in 1977 and 1979, and the third was scheduled for late 1983). American scientists have reported excellent cooperation from their Soviet colleagues not only in these biological satellite programs, but also in the exchange of data from planetary flights (particularly Venus) as well as biomedical data from the Soviets' long-duration manned spaceflights (the longest such flight to date has been 211 days, compared with 84 days for the United States).

U.S.-Soviet cooperation cooled following the Soviet invasion of Afghanistan in 1979. The 1977 agreement expired in May 1982, and President Reagan decided not

to renew it because of Soviet involvement in Poland. Thus, as of the end of 1982, there was no official cooperative agreement between the two countries. Two programs begun under the 1977 agreement were allowed to continue, however: the biological satellite mission mentioned above and an international program for satellite-assisted search and rescue, called COSPAS/SARSAT. A Soviet satellite carrying the first of a new generation of transponders, capable of pinpointing aircraft and other vehicles in distress, was launched in the summer of 1982 and within a short time had been responsible for the safe return of a three-man airplane expedition that had crash-landed in Canada. A U.S. transponder was launched on the NOAA-8 weather satellite in 1983, and a second Soviet satellite was also launched in 1983.

The European Space Agency was established in 1975 as a merger of two separate organizations for developing launch vehicles (ELDO, the European Launch Development Organization) and satellites (ESRO, the European Scientific Research Organization). The United States had a history of cooperation with ESRO that continued with the creation of the new agency. ESA now has eleven member countries (Belgium, Denmark, France, Germany, Italy, Ireland, the Netherlands, Spain, Sweden, Switzerland, and the United Kingdom), two associate members (Austria and Norway), and a technical agreement of cooperation with Canada.

Already mutterings can be heard that NASA is attempting to stimulate international support in order to make it more difficult for the Reagan administration, and eventually the Congress, to reject the space station idea.

Extensive cooperation has taken place between the United States and ESA, and the largest of these programs was ESA's development of a module called Spacelab for use with the U.S. space shuttle. Under the terms of the original agreement, signed in 1973 with ESRO, the Europeans designed, developed, manufactured, and delivered one Spacelab module free to NASA, which had the option to buy additional units. The pressurized unit fits inside the cargo bay of the space shuttle, providing a shirt-sleeve environment for scientists to conduct experiments. The agreement benefited both sides, providing the United States with a needed component of its space transportation system while European industry gained an opportunity to expand into new technological areas.

The first Spacelab was delivered to NASA in the spring of 1982 and was scheduled to fly into space in November 1983. Although difficulties were encountered, primarily because of changing NASA requirements which in turn led to redesign of certain Spacelab components, the overall program has been quite successful. The major ESA disappointment is that NASA has agreed to purchase only one additional Spacelab unit, but the Europeans are promoting the concept of building permanent space stations by docking several Spacelab modules together. At the very least, the knowledge gained by ESA and by European companies will put them in a favorable position to participate in a manned space station program, should the United States choose to pursue one, and it could enable them to build space stations of their own.

Another type of cooperation is exemplified by a 1975 program with India called SITE (Satellite Instructional Television Experiment). In this instance, the United States lent its ATS-6 satellite (Applications Technology Satellite 6) to India for one year in order to perform experimental broadcasts of television programs to remote villages. Programming was developed by the government of India to provide instruction in health, family planning, education, and agriculture. The programs were broadcast in eight languages (Hindi, Kashmiri, Bengali, Oriya, Marathi, Gujarati, Tamil, and English) directly to small receivers in 2,200 villages. Another 2,000-3,000 villages were able to receive the broadcasts through secondary-transmission methods.

The experiment was considered a tremendous success, and led to the development of a satellite by India for continuing these activities. The satellite, Insat 1, was launched by the United States on a reimbursable basis in April 1982, but a problem with the fuel supply led to the cessation of operations in September of that year. A back-up satellite, Insat B, was launched in 1983 and became operational in October, continuing television broadcasts to remote villages and providing point-to-point communications and meteorological information.

Where the Problems Are

The vast majority of cooperative programs have been extremely successful, but I would be remiss not to mention a few of the difficulties that have arisen in recent years. By and large, these problems have not been caused by the U.S. agencies involved in program implementation, but rather by budgetary constraints within NASA, new concerns about technology giveaway, and U.S. policy regarding launch assurances for foreign countries.

In 1979, NASA and ESA signed a memorandum of understanding to conduct a program called the International Solar Polar Mission (ISPM, formerly called the

Out-of-the-Ecliptic Mission) for launch in 1983. The two agencies were each to provide one spacecraft for studying the polar regions of the Sun. Such a study would require the spacecraft to fly out of the plane of the ecliptic (in which the planets orbit the Sun), requiring a great amount of energy. Thus, the mission envisioned sending the two probes toward Jupiter, where the giant planet's gravity field would be used to swing the spacecraft up and out of the ecliptic and back toward the Sun. With two spacecraft, simultaneous readings could be made of both poles. Besides providing one of the spacecraft, NASA agreed to launch both spacecraft, provide tracking and data acquisition services, and give ESA a radioisotope thermal generator (RTG) to power its spacecraft.

The program encountered funding problems from the very beginning. NASA requested ISPM as a new start in its FY 1980 budget, and although the program was approved by Congress, the chairman of the House Appropriations subcommittee having jurisdiction over NASA programs sent a letter to the NASA administrator in December 1979, directing NASA to postpone the mission for two years. One problem cited by the committee was the delay encountered in the development of the space shuttle which would be used as a launch platform for the spacecraft. Moreover, the committee was concerned that the upper stage that was planned to send the two spacecraft on their journey (the inertial upper stage, IUS) would not be adequate for the job, and NASA should develop a high-energy upper stage (Centaur) instead. Although NASA was not persuaded by these arguments, the agency subsequently postponed the launch of ISPM to 1985 as a budget move.

In the spring of 1980, the House Appropriations Committee recommended in the FY 1980 supplemental appropriations bill that ISPM be terminated and that some of the money appropriated for FY 1980 be rescinded. In response, several member countries of ESA formally protested to the State Department, which then came to the aid of the program in Congress. The program was saved, but only temporarily.

The final blow to ISPM came in 1981 when President Reagan submitted his first budget request to Congress, which recommended termination of the U.S. spacecraft for ISPM, although support for the ESA spacecraft (launch, tracking, and data acquisition as well as the RTG) was maintained. This action was taken unilaterally, without prior consultation with ESA. At the same time, NASA decided that it would develop the Centaur upper stage instead of the IUS after all, thus necessitating changes in the ESA spacecraft.

Once again, protests were lodged with the State Department and NASA, but this time to no avail. ESA Director General Erik Quistgaard, in testimony before the House Science and Technology Committee, reminded the members that ESA had chosen ISPM over several other potential scientific programs because of the value it attached to cooperation with NASA, and that ESA had already spent $100 million on the program. Congress provided NASA with $3 million to keep the program alive, but the Office of Management and Budget (OMB) informed NASA that it would not support funding for the program in future years, although it would allow NASA to reprogram funds from other space-science projects.

One can expect that the European Space Agency will want certain guarantees from NASA in order to prevent unilateral cancellation of cooperative programs. ESA will, at the least, want to limit its financial liability in the event of a cancellation.

After considering several options, including the possibility of purchasing a spacecraft from ESA, NASA finally decided that it could not afford ISPM without OMB support.

ESA later decided that it would continue with its spacecraft plans, but sought assurances from the United States that future budgetary actions would not terminate NASA's promise to launch the probe, provide tracking and data acquisition services, and provide the RTG. Although ESA sought an earlier launch opportunity as recompense for U.S. cancellation of its spacecraft, the launch date for the mission has slipped an additional year; the Centaur upper stage will not be ready until 1986.

Assessment of the long-term impact of the ISPM incident is difficult because no further ESA-NASA agreements have been signed since then. ESA has continued to express interest in cooperating with NASA on space-science programs (and possibly on a space station), but one can expect that the agency will want certain guarantees written into future memorandums of understanding in order to prevent unilateral cancellation of such programs or at least to limit its financial liability in the event of a cancellation. NASA faces the problem, however, of having to place contingency clauses in such agreements, to the effect that continuation of a given program is subject to appropriations which make that program vulnerable to annual reviews by both the administration and the Congress.

Another type of problem encountered in international

programs because of budget constraints has to do with continuity of effort. Only two examples will be cited here: Landsat activities and communications support to some Pacific islands.

The Landsat program provides multispectral data that can be used to survey natural resources, to study the effects of pollution, to assist in land-use planning, and to monitor crops and provide crop-yield estimates. The United States has launched four Landsat spacecraft and one more is planned, but beyond that the future of the program is uncertain. The government wants the program to be taken over by the private sector, but since there is not yet a large enough market for land remote-sensing data to guarantee a profit, there has been a dearth of proposals by the private sector to take over the program without government subsidies. Thus, users in foreign countries (as well as in the United States) are concerned that they might invest large amounts of money, either in purchasing Landsat receiving stations or in training personnel to use the data, only to have the United States terminate the spacecraft segment. Another aspect of the Landsat problem is that programs providing for direct U.S. support (formerly through NASA and currently through AID) for the training of foreign scientists in the interpretation and use of Landsat data are in danger of being terminated because of budgetary constraints.

The 1975 Apollo-Soyuz project, the most visible example of international cooperation, was notable primarily because it involved cooperation between two traditional space competitors.

The lack of continuity in U.S. programs is also evident in the communications area. The PEACESAT program, for instance, has provided communications services to certain Pacific island nations since 1971, using the ATS-1 satellite. The satellite is now at the end of its lifetime, and there is no satellite with which to carry on this service. Suggestions have been made for using one of the older INTELSAT satellites, but that would require installation of different ground stations. Another option is to use transponders on one of NASA's tracking and data-relay satellites, but that would require repointing one of the satellite's antennas (and NASA has indicated an unwillingness to do so). Thus, this communication service may end in the near future.

The debate over technology transfer has many components. Technology that the United States provides to other countries might become an instrument of competition with U.S. companies. Technology transferred to a country with which the United States has strained relations might be diverted to military purposes. And technology initially transferred to a friendly country might end up in the hands of a nation with which the United States is not so friendly, either through the capture of U.S. equipment during the overthrow of a friendly government or because a friendly country serves as an intermediary between the United States and an unfriendly country. An example of the latter is offered here.

In 1978, the Arab League, comprising twenty-one Arab countries and the Palestine Liberation Organization, decided to purchase a regional communication satellite system. This satellite system, ARABSAT, will consist of three geostationary communication satellites. The ARABSAT contract was won by Aerospatiale, a French company, teamed with Ford Aerospace in the United States.

In order to provide Aerospatiale with satellite technology, Ford Aerospace required a technology export license, which must be approved by the Senate. In the fall of 1981, the State Department forwarded the request for such a license to the Senate. Unfortunately, this request came shortly after a stormy Senate debate over the provision of AWACS technology to Saudi Arabia, resulting in raised concerns about technology transfers to the Middle East.

When it was learned that the satellite system would be used by the Arab League, which includes countries currently out of favor with the United States, several members of the Senate felt that the export license should be denied. The State Department withdrew the request, and several weeks of briefings by Ford Aerospace (which would have lost $20 million and 5,000 jobs), the Department of Defense, and the State Department followed. Finally, the senators relented, realizing that the technology was being transferred to France, not to Arab countries, and that the satellites themselves would be in geosynchronous orbit, well out of the reach of any country. The request for an export license was reintroduced and not opposed. A major problem resulting from this controversy is whether U.S. companies will be considered reliable international partners in such endeavors in the future or whether U.S. government approval will be required before a foreign company will sign such an agreement.

Yet another type of problem encountered in the international space business relates to launch assurances. In this case, it is a matter of what types of satellites the United States will agree to launch for another country, even if that country is paying for the launch. The United States, for example, will not launch satellites for other countries when its national security might be adversely affected. The assumption can be made that this proscrip-

tion would include military reconnaissance satellites, which may be desired by other countries. Nor will the United States launch satellites that would interfere with its responsibilities under other international agreements; a case in point is the INTELSAT agreement.

The United States sponsored the formation of INTELSAT in the 1960s (and, in fact, INTELSAT is a good example of a highly successful U.S. international space initiative). One section of the INTELSAT charter states that signatories must agree not to launch satellite systems which might cause economic harm to the INTELSAT system—that is, INTELSAT and INTELSAT alone will provide international satellite communication services. In 1967, however, Germany and France decided to develop a satellite system called Symphonie, for launch in 1974, that would be capable of providing communications between Europe, Africa, the Middle East, and North and South America. Asked to launch the satellites, the United States responded that such a system would be competitive with INTELSAT and that the United States therefore could not provide launch services without violating the INTELSAT agreement.

Eventually, the two Symphonie satellites were launched by the United States after Germany and France formally stated that the system was experimental, not operational. Although plans were already under way at that time for constructing a European launch vehicle capable of placing communications satellites in orbit, the Symphonie incident is often credited with having provided the final impetus to the Europeans to construct their own launch vehicle (Ariane) so they would not have to depend on the United States.

It should be noted that a number of regional communication satellite systems (such as ARABSAT) are now planned. To date, these regional systems have been approved by INTELSAT on a case-by-case basis to ensure that they provide regional rather than international service. A 1982 decision by INTELSAT to approve a European regional satellite system being built by the EUTELSAT consortium for only a five-year period, after which another review will take place, has raised the ire of several European countries. With the growing interest by individual countries and groups of nations to have their own satellite systems, INTELSAT will almost certainly have to review its position on competitive systems if it is to survive through the 1980s.

The United States may also have to review its policy regarding what types of satellites will be launched. While the United States cannot be expected to launch satellites that might negatively affect its national security, the question of which other categories of satellites might also be refused is not so clear. This issue will become increasingly important as nongovernmental entities such as Space Services Inc. begin providing launch services.

With respect to international space policy, the future appears quite bleak. Some issues—relating to direct-broadcast satellites, remote sensing, and access to geostationary orbit—have been debated for more than a decade.

The Politics of Cooperation

In addition to the practical, scientific, economic, and national security aspects of international space cooperation, there are definite political components. These can take several forms. For example, NASA has been accused (with increasing frequency) of using international cooperation to win approval for its programs, both within the administration and the Congress. Whether or not the allegation is true, during the late 1970s, when NASA's space-science budget began to dwindle, an oft-repeated NASA theme in testimony before congressional committees was that other countries were participating in a particular program and that its cancellation would therefore create international discord. The ISPM is a case in point.

This approach worked quite well until the Reagan administration, when such arguments became ineffective within the executive branch (it was the administration, not Congress, that canceled ISPM). Nevertheless, NASA has been trying to persuade the administration to support construction of a space station as the next major NASA program. Such approval has not been forthcoming, and NASA is reportedly embarrassed by the fact that others (notably ESA and Japan) are publicly offering to cooperate with NASA in such an endeavor. Already mutterings can be heard that NASA is attempting to stimulate international support in order to make it more difficult for the administration, and eventually Congress, to reject the space station idea.

Another way in which politics influence cooperation is exemplified by the current state of U.S.-Soviet cooperation. As noted, there are no longer any formal cooperative agreements between the United States and the USSR. The only existing U.S.-Soviet space programs are continuations of two that had begun earlier: the search-and-rescue satellite program and the biological satellite program. (This latter program is also interesting from a political point of view because of the pressure brought to bear on Congress by antivivisectionists who,

concerned about the treatment of the two rhesus monkeys that will be flown, want the flight canceled. Apparently they do not realize that the monkeys are being provided by the Soviet Union, so no U.S. action can prevent the flight.)

International politics can also play a role in space activities, although less in specific programs (such as scientific probes) than in overall policy. The United Nations

---

If it is to survive through the 1980s, INTELSAT will almost certainly have to review its position on competitive satellite systems.

Committee on the Peaceful Uses of Outer Space (COPUOS) serves as a forum for the discussion of international space issues. Through its legal and scientific and technical subcommittees, recommendations are made for treaties and other agreements on international space issues. Five treaties have been developed by COPUOS, of which the first four are in force: the 1967 Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies (the Outer Space Treaty); the 1968 Agreement on the Rescue of Astronauts, the Return of Astronauts, and the Return of Objects Launched into Outer Space; the 1973 Convention on International Liability for Damage Caused by Space Objects; the 1976 Convention on Registration of Objects Launched into Outer Space; and the 1979 Agreement Governing the Activities of States on the Moon and Other Celestial Bodies. The United States is a signatory to all but the last of these.

Other issues debated within COPUOS include principles governing direct-broadcast satellites and remote-sensing data, the use of nuclear power sources on spacecraft, the definition and delimitation of outer space, use of geostationary orbit, and technology transfer. Besides the COPUOS activities, the Committee on Disarmament, which is closely associated with the United Nations, is considering issues involving the "militarization" of space and whether to establish an international agency to allow the UN to monitor treaty compliance in times of crisis by means of reconnaissance satellite data.

All of these issues were discussed in August 1982 at the Second UN Conference on the Exploration and Peaceful Uses of Outer Space (UNISPACE '82). The United States was one of ninety-four countries represented at the conference, which was sponsored by COPUOS and was to serve as a forum for demonstrating the advantages of space activities to developing countries (particularly in such areas as remote sensing and communications).

The two-week conference, rather than focusing on technical subjects, became embroiled in a controversy over whether the conference report should include language expressing the concern of the international community over the perceived "militarization" of space. The United States contended that the topic of militarization had been referred to the Committee on Disarmament and was therefore inappropriate to discuss at UNISPACE '82, which was sponsored by COPUOS. All the other countries thought it was quite appropriate since the military uses of space can affect peaceful ones. COPUOS, moreover, has a direct interest in the topic since it originated the text of the 1967 Outer Space Treaty, which addresses the military uses of space in Article 4 (banning the use of nuclear weapons or other weapons of mass destruction in space). After two stormy weeks of debate, three paragraphs reflecting concern about the arms race in outer space were finally adopted. This language was a partial victory for the United States, since it wanted to differentiate between military uses of space (which include activities such as reconnaissance, communications, and navigation) and the arms race in outer space, which Washington perceived to be the cause of the international concern about military activities in space.

Other controversial topics discussed at UNISPACE '82 mirrored debate within COPUOS over the past decade. The dispute over whether a country should have the right of prior consent with respect to the television signals transmitted into its borders by direct-broadcast satellites (DBS) was not resolved at UNISPACE '82. During the UN General Assembly meeting in the fall of 1982, however, a resolution was passed which adopted draft principles that had been developed in COPUOS but had been opposed by many Western nations (including the United States). The resolution has the status of a nonbinding recommendation; its impact is therefore unclear.

Nor was the question of whether a country should have prior consent over the distribution of satellite remote-sensing data on its natural resources resolved at UNISPACE '82, and this issue remains under discussion within COPUOS. As in the case of DBS, the United States opposes restrictions on the distribution of data, citing its free-flow-of-information doctrine.

The issue of guaranteed access to geostationary orbit (GEO) was also highly controversial at UNISPACE '82. A satellite placed in GEO, located 35,800 kilometers above the equator, maintains a fixed position relative to any point on earth and is therefore quite useful for communications satellites. Developing countries are concerned that developed nations will use all the "good" orbital slots and frequencies in GEO, so that none will be available when they want to launch such systems. Con-

sequently, the developing countries want "a priori" plans to be established whereby every country would be guaranteed a place in GEO, whether or not the nation has a plan to utilize it. Developed countries generally oppose such planning because it would deny them access to orbital slots and frequencies which might never be used by the countries to which they are assigned.

This issue is primarily debated under the auspices of the International Telecommunication Union (ITU), a specialized agency of the United Nations. An a priori scheme was negotiated for two-thirds of the world in 1977, for direct-broadcast satellites operating at the 12-gigahertz frequency range, and in 1983 a separate ITU meeting decided the planning scheme for the remainder of the world (North and South America).

The future of international cooperative space programs looks bright if for no other reason than the tight budgetary conditions throughout the world. Nations are becoming increasingly intrigued by the possibilities for commercial applications and scientific endeavors on the space frontier. With cooperative ventures, more can be accomplished.

Despite the ISPM incident, ESA is still interested in cooperating with the United States, and notwithstanding current tensions between the United States and the USSR, one can hope that relations will improve and that new cooperative endeavors can be started in five to ten years. Japan has shown considerable willingness to cooperate with the United States and has plans to select an astronaut to fly on the space shuttle, as do Australia, Britain, Canada, and France. Other countries may also have a chance to fly their own astronauts on the shuttle—President Reagan made such an offer to Brazil at the end of 1982. The Soviets are also flying cosmonauts from foreign countries, and ten have flown already (from Bulgaria, Cuba, Czechoslovakia, East Germany, France, Hungary, Mongolia, Poland, Rumania, and Vietnam). Space is becoming truly internationalized.

The biggest problem confronting the United States in future international space ventures is the budgeting process in which OMB and Congress make yearly decisions on whether or not to continue a program, rather than approving a project for its lifetime. It is not likely that the budgeting process will change, and this raises questions about how the United States can prove that it is a reliable international partner.

With respect to international space policy, the future apears quite bleak. Issues such as prior consent for direct-broadcast satellites, remote sensing, and access to GEO have been debated for more than a decade, and there is little hope that an amicable resolution will ever be reached. Thus, the viability of the international structure for resolving these disputes is being questioned; although, in all fairness, the utility of the UN system as a whole—not just those components that deal with space—has been a matter of great concern to the Reagan administration. Hence, the United States threatened to pull out of the ITU and possibly the UN itself because of a highly politicized ITU meeting in 1982. In that case, the meeting of the ITU, which is theoretically a technical organization for allocating the radio frequency spectrum and orbital slots, degenerated into a political free-for-all when some countries attempted to expel Israel because of its activities in Lebanon. The issue had nothing to do with the agenda of the meeting, but brought to a halt all work at the conference for most of its six weeks. Future U.S. participation in the ITU remains in doubt.

Bilateral and multilateral space cooperation should thrive, but it should be mentioned that competition will also increase. The ESA Ariane launch vehicle, despite two failures out of its first six launches, poses a real competitive threat to the U.S. space shuttle. France and Japan have developed advanced technology for communications satellites, and France is also planning to launch a remote-sensing satellite that will compete with the U.S. Landsat. While cooperation has been a major component of the U.S. space program for the past twenty-five years and will remain so for the indefinite future, competition is likely to play an increasingly important role in setting the stage for the long-term exploration and exploitation of space.□

Gold Rush in the Clarke Orbit

Joseph N. Pelton

It is remarkable how consistently innovations and "miracle breakthroughs" give rise to new and unsuspected social, economic, and political problems. The use of fire is the ancestor of today's energy problem. Urban renewal problems would never have happened without the invention of farming, which made possible permanent human settlements. At the turn of the twentieth century, the members of the London City Council were agonizing over a major concern that they feared would bankrupt the city treasury—namely, how (short of financial disaster) hundreds of tons of horse manure might be removed from the streets of their fair city. The introduction of the horseless carriage was, in its day, greeted as an ecological and financial godsend for the keepers of the city's purse. The automobile, like hundreds of major technological developments before and after, has stimulated progress, while at the same time giving rise to new and unexpected social issues and problems.

Clearly it is difficult to project the future and visualize the development of new industries; once established, however, new services and products soon produce dependencies. Our modern, sprawling cities are totally dependent on modern transportation and communications systems. Although automobiles, chemicals, and computers now give rise to "problems," we cannot just stop using them—at least not without causing serious disruptions to society, perhaps even risking severe damage to modern civilization. Abandonment of modern technologies is, in a practical sense, nearly impossible. This "impossibility factor" certainly applies to our global talking machines—the communications satellites. Pull the plug on the emerging network of domestic, regional, and international satellite communications systems that exist around the world and one is likely to pull the plug on the global economy.

Given the size of the satellite communications industry, it is remarkable that it really all began less than twenty years ago. The entire industry, including satellites, earth stations, launch services, insurance, tracking, telemetry, and command operations, plus the value of the services they carry, will probably near $100 billion by the late 1980s., with perhaps 90 percent of this involving services and 10 percent representing equipment and facilities.

In April 1965, the world's first transoceanic satellite system, known as INTELSAT, was created. At the end of its first year of operation, this satellite system had in service only seventy-five voice circuits. In those days, all telephone service on the satellite had to be surrendered to allow a medium-quality black-and-white television channel to be transmitted across the Atlantic Ocean.

It was from these modest beginnings, however, that the phrase "live via satellite" became a part of our contemporary culture. By 1969, three INTELSAT satellites (positioned over the Atlantic, the Pacific, and the Indian Ocean regions) allowed some 500 million people, the world over, to see the first moon landing live. From the embryonic satellite system inaugurated by Early Bird in 1965, a vast global network, including scores of domestic and special-purpose communications satellite systems, has now emerged. These systems are almost unrecognizable, in terms of scope and complexity, when compared to the simple devices of the early days.

The INTELSAT system now carries virtually all live international transoceanic television broadcasts, as well as 60,000 full-time telephone channels, on more than 1,100 preassigned pathways to interconnect more than 160 countries, territories, and independent possessions around the globe. Furthermore, domestic communications are provided by INTELSAT, under long-term space-segment leases, to more than 20 countries. This service is expected to grow to involve more than 40 countries by the mid-1980s. Separate domestic and regional satellite systems now in operation or planned presently number more than 50. An astonishing array of some 120 communications satellite systems will inhabit geosynchronous orbital space by the mid to late 1980s. Yet, at the consumer level, this proliferation of communications satellites and the growing dependence on satellite communications is invisible and would be noticeable only if these vital services were to disappear.

What's the Problem?

The communications satellites of the 1980s, unlike their forebears of the late 1950s and early 1960s, are complex devices that are typically launched into geosynchronous orbit, sometimes called the Clarke Orbit. There they can continuously provide a wide range of communications services to users who access the satellites through ground antennas. These multibillion-dollar

satellite services (which include telephone, telex, facsimile, electronic mail, television, video conferencing, computer networking, and data communications) are now vital means of national and global communications. These new satellite-delivered services are more cost-effective and versatile than past ways of communicating.

What, you may ask, could possibly be wrong with all this? Unfortunately, the answer is, plenty. First, there is the issue of transborder information flow. Communications satellites are able to relay information across international boundaries, thus giving rise to concerns about privacy of information, the intrusion of foreign interests into domestic economies, and unwanted political, cultural, commercial, or religious messages being beamed into a country without the cooperation or permission of the local government. Particularly within the United Nations and UNESCO, these issues have been given increasing prominence; serious rifts between North and South as well as between East and West have occurred. Many countries are moving to create national laws to protect their "domestic industries" in the transborder data-flow struggle. (It is ironic that the International Telegraph Union, now the International Telecommunication Union [ITU], was created in 1865 to cope with this same issue of transborder data flow, though in the context of the telegraph.)

A second major concern relates to the issue of international equity and equality of access to communications satellite services. Since deployment of communications satellites requires a sophisticated technological base and considerable financial resources, many Third World countries have become very concerned about the increasing number of geosynchronous communications satellites being deployed by the developed countries. These concerns include the fear that by the time Third World countries are ready to deploy or utilize their own communications satellite system, there may be insufficient locations remaining in the Clarke Orbit. These issues came to a head at the ITU's World Administrative Radio Conference (WARC), held in Geneva during 1979. This concern was most pointedly expressed in terms of opposition to the status quo principle of first come, first serve.

A third series of problems relates to competition. There is today competition between technological media such as satellites and submarine cables and, by direct extrapolation, between aerospace and cable manufacturers. Likewise, there is an emerging competition between domestic, regional, and international satellite systems. This process of competition has been further promoted by the U.S. government's attempt to "deregulate," "commercialize," and "diversify" the market in the field of telecommunications. Finally, there is an emerging rivalry among the different types of satellite communications service requirements, such as fixed satellite services versus broadcast satellite services, mobile satellite communications services, or radio-location (radar) services.

Some have suggested that communications satellites should ultimately be reserved for those applications which best make use of the unique characteristics of satellites, such as multipoint-to-multipoint broadcasting or mobile services. Others strenuously argue that satellite communications facilities should continue to provide all forms of services, with demand and marketplace considerations being the prime consideration.

The resolution of these questions will largely depend on which radio frequencies are made available for satellite communications within the framework of the ITU international negotiations and decisionmaking process. Over the next five years, technical debates will focus on which higher radio frequencies are to be utilized for satellite communications, and when; whether certain applications or geographic areas should be given prime access to the lower (more desirable) radio frequencies; and whether accommodation and agreement can be reached between developed and developing countries to meet all technical, operational, and service needs.

The issue of frequency allocation and use within the ITU forum involves not only communications satellites but terrestrial communication applications, as well. There is frequently a dispute over whether terrestrially based use of the lower radio frequencies should be primarily for telecommunications services (a view primarily expressed by developing countries) or primarily for broadcasting and mobile communications services (primarily espoused by developed countries). Other technology-related issues have to do with the continued use of "conventional" dedicated communications satellites (which have now been in service for the past fifteen to twenty years) versus the concept of large and increasingly complex multipurpose space platforms. Some feel that consolidation of a large number of service requirements and a range of different radio frequencies into a single, very large spacecraft makes much more efficient use of the geosynchronous orbit and is preferable to continuing the trend toward proliferation of conventional satellites. The above issues, which of course have many key technical aspects, involve conflicting industrial and economic interests, particularly with respect to the U.S., Japanese, and European aerospace, communications, electronics, and cable industries.

Although this has hardly been a comprehensive list of the issues that have arisen from the successful development of the communications satellite over the past fifteen or twenty years, it does suggest the range of economic, political, and social issues confronting the field today. Since I cannot here explore all these issues in depth, I shall focus attention on what is probably the primary political and technological issue now confronting the ITU, INTELSAT, and the many national communications satellite industries (particularly in light of the WARC meetings scheduled for 1985 and 1987). How can equitable and beneficial access to the geosynchronous orbital arc be assured to all countries, whether they are developing, industrializing, or highly developed information societies. In particular, will such access be based on opportunity, resources, or need?

Into the Diplomatic Maze

To understand the dimensions of this problem and the international procedures to deal with the issue of orbital assignment and geosynchronous arc, one must know more about the major institutions involved. These include the following:

- *The International Telecommunication Union*, responsible for international regulations concerning the use of all the world's electromagnetic spectrum for communications and scientific research.
- *The International Frequency Registration Board* (IFRB), the unit within the complex ITU structure which maintains the master register of frequencies and records the successful conclusion of intersystem coordination agreements for all satellite systems.
- *The International Committees on Telegraph and Telephone and the International Committee on Radio* (in their French abbreviations, the CCITT and the CCIR, respectively). These international committees develop internationally agreed recommendations for communications standards in the fields of electronic telecommunications, radio, telegraphy, and television.
- *The International Telecommunications Satellite Organization* (INTELSAT), which operates under two international agreements and now provides two-thirds of the world's overseas telecommunications services for some 160 countries, territories, and independent possessions, as well as domestic communications services for more than 20 countries.
- *The International Maritime Satellite Organization* (INMARSAT), an entity created under two international agreements for the purpose of providing international maritime satellite services.
- *UNESCO*, the UN specialized agency responsible for communication at the level of mass media, journalism, and culture. Recently, through a new subsidiary entity known as the International Programme for Development of Communications, UNESCO has become increasingly involved in transborder data-flow and telecommunications development issues.

Besides the above, there is a host of other orgnizational entities engaged in the provision of satellite communications service facilities. Today, literally thousands of people are involved in the very complicated field of international diplomacy vis-à-vis satellite communications.

Every twenty years, in theory, the International Telecommunication Union holds a World Administrative Radio Conference, among its entire membership, to review and revise global radio regulations, including the table of radio-frequency allocations. The ITU's radio regulations are a vast complex of recommendations, tables, and charts, sprinkled liberally with highly technical explanatory footnotes. This forbidding document, together with masses of CCIR and CCITT documents, forms the foundation of the worldwide regulatory system for satellite communications as well as for all other modern forms of communications. These formidable radio regulations are of the utmost importance not only to the multibillion-dollar satellite communications industry but, indirectly, to an increasing portion of the world economy as a whole.

The field of modern telecommunications is evolving very rapidly, not only technologically but also in its political and social dimensions. Consequently, the practice has evolved of holding a large number of international conferences, at much more frequent intervals than the traditional "every 20 years," in order to deal with this complexity. Thus, recent years have seen specialized administrative conferences on satellite broadcasting, medium-frequency broadcasting, maritime communications, and so on. These might be thought of as "kissing cousins" to a full-scale WARC. In addition to dividing the WARC process into sectors related either to services, technologies, or radio-frequency ranges (or indeed a combination of these), the ITU has found it useful to divide the world up into three regions: *Region 1*, Europe, Africa, and the Middle East; *Region 2*, the Americas; and *Region 3*, Asia and Australasia. Regional conferences are also held to deal with subjects relating to one or another specific issue. These sessions, then, called Regional Administrative Radio Conferences (RARCs), are like third cousins once removed from the twenty-year-old WARC. In 1983, for instance, there will be an RARC for Region 2, devoted to the allocation of radio frequencies for broadcasting satellite services.

Thus, one must contend with a labyrinthine maze of activities within the ITU structure. These include the complex intricacies of the CCIR and CCITT, with nearly fifty working groups; the WARC's own special preparatory meetings; the Specialized Administrative Radio Conferences plus the RARCs; the plenipotentiary meetings of the ITU; and the meetings of the ITU's Administrative Council. Seldom does a week go by that there is not some ITU meeting held somewhere in the world. On the one hand, this elaborate process is a remarkable example of international cooperation at the scientific and technological level. It has been said that one form of tyranny is to impute simplicity where it does not exist. Complexity is a necessary response to the "high-tech," rapidly developing field of telecommunications. On the other hand, the necessity of having a high level of expertise to participate in ITU meetings is in itself a major concern of the developing countries, which lack both the expertise and the financial wherewithal to participate at the same level as such advanced countries as the United States, the Federal Republic of Germany, France, and Japan.

The ITU, which is the world's oldest universal-membership intergovernmental international organization, has been swept up in the winds of change during the past decade and a half. Initially, the ITU was designed to coordinate European telegraphy. Reconstituted as the International Telecommunication Union in 1932, the ITU was given a broader mandate: to cover all elements of telecommunications and particularly to establish regulations for the practical and scientific use of the

electromagnetic spectrum. As late as 1945, the ITU had a total membership of just over 70 countries. As such, it was largely dominated by OECD (Organization for Economic Cooperation and Development) countries. However, by 1982, the rapid emergence of new countries had pushed the membership of the ITU to more than 150. The largest specialized agency in the UN system, the ITU has more members than the United Nations itself. Since the ITU operates on a one-vote-per-country basis, the historical predominance of OECD countries in the ITU has thus dramatically changed at a time when the level of technical complexity has greatly increased. Further, the global view of telecommunications has shifted, with modern communications being increasingly recognized as a primary strategic and economic force in today's world.

At the last major World Administrative Radio Conference, held at Geneva in 1979, the ITU's radio regulations were reviewed and extensively revised. Certain issues, however, were not resolved and led to the adoption of a resolution (No. BP-1) to hold two conferences (now scheduled for 1985 and 1987) in order to determine the means whereby all countries of the world could be guaranteed equitable access to the geosynchronous orbit for purposes of satellite communications. Preparations for these major conferences have already begun in earnest in the United States and elsewhere. In the United States, for instance, an advisory committee of experts, with over 100 members and a network of subcommittees, is hard at work developing positions, strategies, and evaluations of options. U.S. governmental staff (particularly in the Federal Communications Commission, NASA, the National Technical Information Service, and the Defense Department) as well as consulting firms are engaged in technical studies, while the U.S. State Department is undertaking preliminary soundings around the world.

Although the U.S. preparations are perhaps the most complex, a somewhat comparable level of activity has also begun in most OECD countries. The level of detail involved is great. In Japan, for example, the National Space Development Agency is developing technical/legal proposals concerning procedures for removing retired communications satellites from geosynchronous orbit. In the United Kingdom, a sophisticated study of the relative merits of using lasers instead of microwave for space-to-earth energy relay has been undertaken.

The Pivotal Issues

Although there are hundreds of technical subjects to be evaluated, discussed, and agreed on at the 1985 and 1987 WARC meetings, the basic policy issues are small in number. There are, in my view, three pivotal issues, which, perhaps surprisingly, are heavily dependent on technical reasoning and studies.

First is guaranteed access to the geosynchronous orbit. The developing countries will likely press for a standardized planning formula of dividing the "orbital arc resources" equally among all countries, regardless of need or ability to use the orbit in the near term. The idea is to protect the "resources of geosynchronous orbital space" for the future. From the developed countries will come alternative proposals—and some of them will be quite innovative, including the following ideas:

- Division of the orbit into broad geographic "regional service sectors," aimed at accommodating regional demands.
- Establishment of interim or short-term procedures to continue first come, first served principles, with penalties or sanctions for overstaying allocation periods.
- Various economic/technical/operational plans to guarantee access to the orbital arc for developing countries, either by tighter spacing of satellites in order to accommodate newcomers or by providing firm commitments that multilateral/multiuser satellite systems such as INTELSAT will provide space-segment facilities and services adequate to meet Third World communications needs. This last might be achieved either through long-term lease of a space segment or through dedicated space segments as provided for under Article 3(e) of the INTELSAT Agreement.

In fact, the final solution might be a combination of these proposals, since a continued INTELSAT policy of leasing capacity for domestic services can be anticipated even in the absence of the WARC negotiations.

The second pivotal issue is defense and governmental versus civilian or commercial applications of space. Radio location (radar) and, to a lesser extent, military space communications, are applications where exclusive use of frequencies is desirable. The parallel growth of defense and commercial/civilian space communications during the 1970s and early 1980s increasingly means that these two types of services (i.e., military and civilian) are in direct competition for radio allocations in the geosynchronous orbital arc. The escalation of this battle, particularly when viewed as a zero-sum game, translates into a difficult, troublesome series of issues to resolve with only a minimum of positive answers in sight.

Small, conventional dedicated communications satellites, versus large, technically complex multi-frequency space platforms or clusters, constitute the third issue. The demands on the geosnychronous orbital arc can be resolved in only a few ways: by limiting the growth of services; by using tighter spacing of satellites with more interference; by using either more efficient modulation, coding, and processing techniques, in order to allow higher throughput in the same satellites, or higher-performance spacecraft, such as large, multibeam orbital antenna farms or satellite clusters, in order to allow manyfold frequency reuse and multipurpose service at a single point on the geosynchronous orbital arc. It is of course possible—indeed likely—that all of the above could happen simultaneously. Philosophically, though, the basic issue has to do with the balkanization of space

through the proliferation of dedicated satellites versus integration of space applications into multipurpose and multiuser programs.

Today, the trend is toward continued satellite proliferation, with each country (indeed, each company or institutional entity) trying to plant its flag or corporate logo in Clarke Orbit. To state the extreme, if each communication satellite system identified for operation by 1985 were to be used as a trend line for projecting the situation in 2025, one could project some 20,000 separate satellite systems! Although this is clearly an impossibility (only some 120 to 180 orbital slots are available in the Clarke Orbit), the planners of satellite services have yet to face the need to consolidate domestic services in a manner similar to that which INTELSAT has done internationally.

Despite the complexity of the issues involved and the many technical, operational, financial, and industrial issues that the use of the geosynchronous orbital arc have generated in the past twenty years, there is no reason for despair. Indeed, for the following reasons, there is a sound basis for optimism:

- *A Strong Motivation toward Research and Development.* The challenge of fiber optics, the demand for new satellite services, the growing revenues from satellite communications, and the tremendous demands upon the Clarke Orbit all stimulate a strong R&D effort to provide new and more cost-effective technologies. Progress in the field since 1965 has been enormous—a result largely fueled by R&D. The prospects for the future are equally bright.
- *Technological Solutions on the Horizon.* A number of technical solutions that can multiply the effective use of the Clarke Orbit are almost within reach. These include on-board signal processing; large, multibeam antennas to allow extensive frequency reuse; space platforms; satellite clusters; and intersatellite links. These technologies should allow an increase of the effective capacity of the world's satellite systems by more than one-hundredfold by the twenty-first century.
- *Workable Institutional Arrangements.* The institutional arrangements within which decisions concerning satellite communications must be made are complex and intimidating to the uninitiated. They are, nevertheless, quite workable. Although improvements might be possible with regard to the structure and operation of the ITU, the IFRB, the CCIR, CCITT, INTELSAT, INMARSAT, and the IPDC, by and large these institutions are coping with significant telecommunications issues with considerable skill and success. The world's telephone and data network is today one of the largest and most smoothly functioning machines known, and the implication of the so-called Integrated Services Digital Network (ISDN) in the 1980s will make it even more so. This amazing achievement is, in part, a testament to the institutional arrangements in this field.
- *Effective Leadership.* Knowledge, competency, and capable administration, rather than political charisma, remain the key assets of leadership in the field of international telecommunications. The secretary general of the ITU is a capable person.
- *A Spirit of International Technical Cooperation.* The UN systems have at times seemed to have fallen victim to petty politics, bloc voting, and endless, unresolved debate. It can be confidently said, however, that the ITU has for the most part escaped these pitfalls. A telecommunications tradition of more than 100 years remains strong; issues are generally examined on their technical merits and are objectively assessed. Peer pressure among scientists and engineers to exclude polemics and to seek sensible and equitable solutions has served telecommunications the world over quite well. One can hope the tradition will continue.

As we reach into outer space to seek better ways to serve the people of our small planet, we also see the extent to which we are committed to a common goal and a common fate. Our earth is only a 6-sextillion-metric-ton mudball—a small planet in a small solar system, on the outreaches of a medium-size galaxy, in a universe studded with hundreds of millions of other galaxies. As we gain this cosmic perspective, the desirability of finding global solutions—not only for telecommunications problems but in all fields of endeavor—will become increasingly clearer. In the field of satellite communications, certainly, the sky is not the limit.□

He has worked in the field of satellite applications since 1965, with North American Rockwell, NASA, George Washington University, the Communications Satellite Corporation, and INTELSAT.

Pilots of Outer Space

B.J. Bluth

Imagine spending six months in a moderate-size motor home, traveling across the United States. You don't have to drive. At the same time, you can't get out and go for a little stroll by yourself. The view is matchless—270 miles straight down to earth and a sunrise or sunset every 90 minutes. The company, however, stays the same day in and day out.

This experience of long-term spaceflight is becoming routine. The Soviets have had three long missions lasting between six and seven months. There is a prime crew of two men, with teams of two or three visitors (one was a woman) who come and stay for a week or ten days. The longest U.S. flight was the eighty-four-day Skylab mission, which ended in 1974. Both countries have plans for more ample stations prepared to hold larger crews. The longer the missions, however, the more difficult the interpersonal, social, and psychological factors become. Valery Ryumin, who has been on two six-month flights, put it this way in his diary:

> Our problem is deeply human. We must now adjust to living together, away from the rest of the world. Robinson Crusoe, after finding himself alone on an uninhabitated island solved problems by himself, accounting to himself. We have to solve ours together, taking into account the feelings of the other. Here we are totally alone. Each uttered word assumes added importance. One must bear in mind—constantly—the other's good and bad sides, anticipate his thinking, the ramifications of a wrong utterance blown out of proportion.

He added that he thought one of O'Henry's comments fit the situation quite well: "All one needs to effect a murder is lock two men into a cabin, 18 feet by 20, and keep them there for two months." There have been no murders yet, but there have been problems.

Generally derived from Talcott Parsons' General Theory of Action, six factors can be used to study the situations and problems that have developed in spaceflight:

- *Environment*. The space environment itself, especially its weightless condition, can affect the way a crew member works and feels. Besides weightlessness, it includes such items as cosmic radiation, isolation, confinement, architecture, technology, tasks, ground control, and the outside world of service, family, friends, other groups, and events. This category also includes equipment design and human-machine relationships.
- *Physiology*. Living in the space environment, a crew member experiences significant bodily changes that affect many of his sensory systems as well as physical, and hence mental, tone. This includes the impact upon the skeletal, muscular, and cardiovascular systems. Space sickness (though it does not usually last beyond seven days) is a good example of impaired effectiveness in the space environment. Other factors that may affect human mental tone by way of physiological changes are related to type or availability of food or to ingredients of the life-support system.
- *Personality Systems*. Individual predispositions of cognition, attitude, motivation, values, and thinking patterns can contribute to error and poor adaptation. Since an individual is not static, but changes in both predictable and unpredictable ways, selection is a useful (but not sufficient) facet of personality evaluation.
- *Social Systems*. The design or organization of systems of authority, roles, schedules, communication patterns, decisionmaking, leisure activities, jobs, and informal interaction is related to the way in which a crew performs its duties, both on the station and vis-à-vis the ground. This category includes systems of rewards and career advancement, manipulation and interchange with and within the environment, social control, and socialization processes.
- *Culture Systems*. Ideas, values, beliefs, assumptions about what is good, bad, important, and real constitute an ongoing background factor in crew activity and in ground-crew interchange. Culture systems have an important effect on performance and expectations.
- *Process*. Events occur in sequences or interrelated strings, becoming unique configurations which form growing cumulations of significance as time passes. A given event, out of context, may seem unimportant but, seen within the context of its total historical progression, can become a matter of great importance.

Furthermore, there is constant interchange with many environments: the technical, immediate interpersonal, and that between the ground and orbiting crews, including families, friends, and the general effect of worldwide events.

Close Calls

Both the American and the Soviet space achievements have been impressive, amply demonstrating the ability of people to live and work successfully in the unique environment of space. However, both programs have also had their share of problems that can be traced to social and psychological factors.

Two missions of approximately six months duration and one of almost seven months have been flown by Soviet cosmonauts in the Salyut 6 and 7 space stations. Prior to each Soviet mission, extensive tests and activities are undertaken by the Group for Psychological Support to ensure the compatibility of the crew members and provide training for the flight. Crews undergo a rigorous program designed to develop self-confidence and emergency survival skills. During each mission, the group constantly monitors the crews to detect signs of stress, and it is responsible for developing compensatory measures. Despite all these precautions, General G. Beregovoi, chief of crew training, reports that crews developed signs of interpersonal hostility about thirty days into the mission and that this situation is a matter of concern, with respect to both flight safety and mission effectiveness. This problem is confirmed by other cosmonauts. Cosmonaut Sevastyanov commented that "joint existence cannot be serene. We had disagreements in flight. . . . The disagreement did not reach a scandal, inasmuch as there was no 'platform' [it would be very hard to "punch" someone is weightlessness]. It was simply fatigue, and frequently simple inattention, which could cause the argument." Cosmonaut Lenov remarks that "the effect of psychological compatibility arises after approximately one month of staying under conditions of group isolation. The longer the flight, the more strongly the given effect appears." Lenov concludes that, despite preparations and training, "it is impossible to ensure good psychological compatibility on a long flight," and there are rumors that Cosmonaut Ryumin wanted to return to earth a couple of months into his second long flight. Soviet scientists have speculated that this problem is caused by exhaustion of the nervous system, the biological toll of weightlessness, informational overload, and constant publicity. However, other studies of Soviet systems suggest that social and cultural system variables are important contributing factors.

The hostility that has appeared in Soviet missions is not confined to the flight crews. There also have been arguments and conflict between the crews and the mission control staff on the ground. One cosmonaut commented that sometimes crews were happy in "autonomous flight without communications from earth. To be alone without constant nitpicking from the earth was sometimes necessary." The crews were reported to have masked their feelings and reactions, withheld information, and on one occasion were rumored to have turned off all communications with the ground for two days.

Crews show mood swings, increases in tension, and difficulty sleeping. They are apparently reluctant to use the games provided by the Group for Psychological Support for relaxation, and often use their leisure time to work. "Rest and work in space have different meaning," according to Cosmonaut Kovalenok. In space you want to "load yourself with work so the time will go faster. Otherwise, you feel that the time slows down, and then you feel the loneliness, or you start thinking of aches, pains, sinus congestion, or your general physical condition." Lack of work to do is related to psychological conditions that, Kovalenok says, are "particularly severe under zero-gravity conditions." In space, a man is in a state of "constant alertness."

Exuberance nearly resulted in tragedy for the Soviet program when Y. Romenenko supposedly forgot to attach a safety tether as he took an unauthorized look outside his Salyut-6 space station. When the rookie Romenenko and the veteran Grechko arrived on Salyut 6, one had to make an early space walk to check the docking port. There was some fear that the automated Progress resupply ships might not be able to dock at the station, possibly forcing the crew to return to earth. Grechko went out into space, and Romenenko was suited up in the airlock, responsible for watching Grechko's life-support systems. Romenenko had heard how beautiful space can be—stars like jewels sparkling on black velvet; colors so beautiful that no photograph could reproduce them. The story goes that the excitement got to him and that he decided to take a little peek—to pull himself up just enough to put his head out the hatch for a look. But as he pulled himself up, his momentum in weightlessness took over, and he floated out. He had not secured his safety tether and soon found himself flailing about, gradually floating away from the spacecraft. Fortunately, Grechko saw him and grabbed his foot. It was more than a close call.

Soviet cosmonauts, like their American counterparts, are trained to follow checklists and to comply with safety requirements without fail. Such a lapse of judgment was a serious mistake—one that is perhaps even more important than Romenenko's small adventure, as it raises questions about the way some people may react in space.

V. Vereschetin, a deputy chairman of the Intercosmos Council, stated at a Moscow news conference that "cosmonauts' efficiency declined during long flights." Cosmonaut Ryumin (who was on both long flights) believes man could stay up longer, but was quoted in *Izvestia* (March 28, 1981) as saying that "after 3-4 months of work in orbit, exhaustion sets in. And if there is not a special need for some sort of very important task, there is no particular sense in pushing a cosmonaut's body to its endurance."

38-036 O - 84 - 12

At a recent conference in Bonn, West Germany, the academician Gazenko reported that "psychological and everyday-life discomfort . . . seems to be inevitable for space operations for the near future," and thus the "duration of space missions may be dependent on nervous-emotional stability of crew members, their psychological compatibility, level of motivation, pattern and stability of various habits, and other factors that can hardly be identified." The question to be asked here, however, is why cosmonauts become fatigued, what affects their stability, and which factors can be identified and changed.

> "All one needs to effect a murder," said O'Henry, "is to lock two men into a cabin, 18 feet by 20, and keep them there for two months."

A number of accidents, near accidents, and problems have also occurred in the American space program. One very nearly fatal incident came about during the Apollo-Soyuz test project as the command module reentered the atmosphere. There had been a number of cockpit errors on this mission, and these included forgetting to set two critical switches for reentry which would have prevented automatic devices from deploying the chutes and from dumping excess fuel and oxidizer from the attitude-control rocket engines. Commander Tom Stafford apparently was distracted and neglected to call for them at the proper time, and the rookie astronaut, Vance Brand, also missed them. As the capsule reentered the atmosphere, the crew began to choke, gag, and gasp as highly corrosive nitrogen oxide gas filled the cockpit. Brand passed out cold, and it took five minutes for Slayton and Stafford to break out the oxygen masks. The effect of such a toxic mixture on the lungs could have been fatal.

In evaluating the reasons for this error and the others that occurred, Astronaut Walt Cunningham suggested that Stafford and Slayton had not trained as much as they should have for the mission and that "the crew did less training *together* than usual, even for those phases of the mission which required close coordination." He cited a heavy social schedule, emphasis on public relations, and the fact that much of the training load was placed on the rookie's shoulders. There was a significant status difference between Slayton and Stafford, on the one hand, and Brand, on the other. Deke Slayton and Tom Stafford were veterans of the U.S. space program and had many years of experience and high positions in NASA. Brand was young and new. This accident was not caused by equipment failure, but by human error, conditioned by social system factors in conjunction with personality and cultural factors. The value placed on social and political activities superceded the need for training, and the influence of status may have inhibited communication between Brand and his superiors.

Scheduling and time pressure are cited as some of the major causes of error on the 1973/74 Skylab-IV mission, which lasted eighty-four days. Since this was to be the last mission for Skylab, many new experiments were added to the flight plan. The crew had not trained for these experiments, however, and it took longer than expected to set up and carry out the new experiments. There were many unanticipated difficulties, yet the ground pressed the crew on in order to take advantage of the precious time in orbit. As a result, the harried crew was plagued by errors, mistakes, and lost data. The problem got so bad, in fact, that Commander Jerry Carr asked Mission Control to have the ground staff completely rework the program, giving the crew more discretion to do their own scheduling from a shopping list of experiments as well as more time to themselves. Once this new system was instituted, the crew's performance improved considerably.

Unique to Space?

Early studies of the social and psychological factors involved in long-term spaceflight started with the assumption that the symptoms, errors, and accidents that occurred were primarily related to the biological ramifications of weightlessness or to the phenomena of isolation and confinement. Symptoms found in either Soviet or American spaceflights included insomnia, irritability, mood fluctuations, fatigue, hostility, vacillating motivation, depression, and stress—symptoms quite similar to those found in isolated and confined environments. However, the list of symptoms that emerged in spaceflight also has much in common with the list of symptoms that develop in environments which are not isolated or confined, but which are associated with the development of stress. Although some spaceflight symptoms can be traced to the effects of weightlessness on the body (these vary in intensity as the body adjusts), there are other systems which can be related to the structural aspects of stress in general and, as such, are subject to alteration.

Environments studied by NASA in the 1960s and considered to be isolated and confined included the Antarctic, submarines, oceanographic research vessels, undersea habitats, simulations, and fallout shelters. NASA itself sponsored many simulations as well as undersea expeditions in order to study the features of isolation and confinement. The symptoms that can be extracted from that literature are as follows: boredom, irritability, depression, anxiety, mood fluctuation, fatigue, hostility, social withdrawal, vacillating motivation, tension, sleep disorders, and lowered performance. Studies made of the stress literature yield the following list of symptoms: boredom, irritability, depression, anxiety, excessive emotion, anger, tension, sleep disorders, lack of concentration, lowered efficiency, defensiveness, and fear.

This research traces the causes of the symptoms to many different sources, many of which can be related to spaceflight situations. Some of these sources are: conflicting definitions of a situation, mismatched work, organization, leadership systems, scheduling, expectations, group size, reduced roles, reduced sensory input, architectural arrangements, group composition, training, communication systems, physiological factors, crowding, loneliness, career development, job design, time pressures and long hours. These studies suggest that many of the symptoms that develop on long flights may not be unique to the space environment and, in fact, may be alleviated by training and careful design of social and environmental features. A few examples from this vast literature follow.

Weightlessness brings about profound changes in the human body, and there should be no discounting the potential impact those changes can have on the psychological readiness of a space station crew. Earthbound studies, however, show that people can mistake socially or psychologically created tension as a biological problem. For example, fatigue and sleep disorders are often a symptom of social or psychological stress. Continued disruption of the sleep cycle increases fatigue while increasing general tension and thus inducing more strain into the situation—a vicious circle.

A recent NASA report also shows that there are clear psychological effects from the alterations in circadian rhythm and the rapid changes from light to dark that occur in orbit. These symptoms included depression, hopelessness, boredom, irritability, negative moods and withdrawal, fatigue, decreased performance, insomnia, anxiety, as well as gastrointestinal and other physical symptoms.

Social and psychological conditions are important with respect to establishing good group relationships. Normally, for example, a person's involvement in a group represents but one facet of his life. There are many groups, many roles, many spaces between groups, and thus many outlets for interests and support. A work group in which one is constantly evaluated is distinct from the family or friendship group, where the individual believes he is accepted and wanted for himself. Ideally, he does not need to be on guard, to prove himself, or to put forth his best effort. As part of a space crew, one combines work and informal life, and all aspects of daily life are carried out in the presence of the same group of people. One is never alone. The "boss" is always nearby. Such a situation automatically places a strain on the crew members because the same group must carry out two different and incompatible functions: work and friendship, evaluation and nonevaluative support. In a space station, there is an additional strain: the situation is potentially dangerous, and survival depends on interdependence. Research shows that such a situation can bring on fatigue, headaches, poor communication, and problems with authority.

To cope with this problem in its two-cosmonaut crews, the Soviets have almost completely abandoned formal hierarchical roles between the crew members. The Americans do have clear hierarchies in place for the space shuttle missions, though it is questionable how salient they are now, since these people have worked together for so many years that they do not depend on formal role structures in their interactions.

There is evidence that groups having an even number of members behave differently from groups having an odd number of members. Even-numbered groups disagree more than the odd-numbered ones and, as a result, suffer more deadlocks. Groups having an even number of members may split into equal factions, which does not usually happen in a group having an odd number because one side always has the numerical advantage. Groups of five usually escape such divisions and are shown to rate high in member satisfaction; dissenters have some group support. As the group gets larger there is more stability, but the lines of communication tend to become focused on the leader, some members becoming more passive. When these groups are total systems, with work and primary relationships being coextensive, the deadlocks, disagreements, and tendencies to soften rules or circumvent the command structure become much more important. Such situations can become a source of strain and error-producing conditions. By keeping groups in odd numbers, some structural generative elements of stress can be avoided.

In space, rest and work have a different meaning. One is in a state of constant alertness.

This seems to have been confirmed in both the Soviet and the American experience. The Soviets, with their crews of two, seem to have had more interpersonal problems than the American crews of three—a result that was predicted in the early 1960s by NASA researchers.

Newcomers into small, cohesive groups often complain of being shut out. A basic trait of group membership is the feeling of togetherness, belonging, and a sense of "us" as opposed to "them." The identity of the group becomes defined by its *distinction from other groups*; out of a desire to preserve this identity, groups often will forget internal disputes while confronting "outsiders." In fact, this phenomenon is often used to provoke internal group cohesion and loyalty.

Some discomfort has been reported by non-Soviet cosmonauts who have visited the Salyut station under the Intercosmos program. The Czech cosmonaut, Remek, reported feeling uncomfortable and left out on occasion.

There were misunderstandings, hurt feelings, and a genuine concern about the problems of language and communication.

Thus, by rotating station crews—one half leaving and the other half staying—two distinct, and possibly antagonistic, groups might be created. If schedules should further tend to isolate the two groups, living and working in small quarters, the potential for distrust, suspicion, and hostility is increased. There may be many unexpected problems if the crews are mixed cultural subgroups or come from multinational backgrounds.

Research has shown that organizational structures should vary with the demands of the job. Jobs involving research require a more open-ended, loosely structured system. Jobs that demand on-site problemsolving require flexibility. And jobs that are precisely defined and broken down into small divisions of labor demand a high level of structure. The formal aspect of an organization (the fit between the task and the normal practices of the organization) must match the climate of the organization (the subjective perceptions people have about the organizational setting). These can be compared on predictable and unpredictable dimensions. Thus, predictable tasks call for a predictable climate, and unpredictable tasks call for more fluidity or flexibility in the climate. On Skylab, however, many unpredictable jobs were scheduled as though they were highly predictable; this created stress for the crew and tension between the crew and the ground personnel who were responsible for the planning.

Numerous studies have also shown that mental health problems, stress, and alcoholism are related to a lack of participation in decisionmaking, a lack of control over the work, or a lack of autonomy. Stimulating some internal regulation of the system by the group, using discretionary rather than prescribed work roles, increasing variety, and decreasing the bureaucratic mode—while keeping in mind the fact that the primary function of these groups is to work—have resulted in significant increases in effectiveness and a decrease in stress-related problems. When Skylab crews were given more control over their schedules, their productivity improved significantly.

A look at some of the problems that developed on the Skylab suggests that a different work design might have reduced some of the difficulties the crew experienced. There were also disagreements between the "scientist astronauts" and the "test-pilot astronauts" during the Apollo programs, resulting in lost, damaged, or eliminated experiments. Such subculture differences could also be a problem on long-term missions if the organizational and decision systems are not designed to recognize the varying assumptions, values, and requirements of the different groups.

Architectural research shows that the design of workspaces and living quarters can have an important effect on mental state. Astronauts and cosmonauts have commented on the use of color (they do not like what is there), windows (there are never enough), noise (there is too much), smells (there are not enough good ones), flexibility in arrangements (one cannot change things), restraints (there are not enough places to put things, and things do not stay put), good traffic flow, organization of public and private sections (there is no place to be "alone"), and the inclusion of "nice" touches such as fish and plants.

Studies show that the sociotechnical design of work stations needs to fit the kinds of mental models needed to operate the facility efficiently under routine as well as emergency conditions. These studies are proceeding in the design of aircraft cockpits, nuclear power plants, as well as computer terminals and general areas. Analyses of space shuttle and Skylab equipment suggest that some design features are conducive to human error or create difficulties in weightlessness.

Different Strokes

The United States and the Soviet Union have completely different approaches to the problems discussed above. In the early days of the U.S. space program, there was considerable concern about the possible psychological effects of space. Numerous tests, studies, and reports followed. Space did not turn out to be as mentally debilitating as was feared, however, and as the astronauts acquired the ability to fly spacecraft instead of just ride them, they also edged out the psychologists and their programs. They seem to have had good reason to do so. Stories and reports suggest that the psychologists were not very sensitive to the feelings and attitudes of their subjects, and that their suggestions were often seen by the crews as too theoretical and lacking in practical application. The result was that no systematic psychological studies were made of the Apollo or Skylab crews, or of the conditions on board the spacecraft that related to mental state, error, and so forth. Psychological studies dropped off dramatically, but did not stop. NASA continued to sponsor university research—work on the kinds of conditions that develop in confined microsocieties, a management study of a spacelab simulation, evaluations of undersea conditions and their effect on mental and interpersonal activities, and some situation studies of oceanographic research ships as well as of male/female crews on supertankers. The results of these studies, however, were not filtered into the design process at NASA and hence have had little impact on flight programs.

Now that NASA is looking seriously at the development of a space station within the century, people in the agency are beginning to look seriously at the social and psychological problems involved in long space missions. Some small studies are being done in-house and by industry, including research on the command and control of varying numbers of mixed crews, work and rest schedules, the influence of diet on astronaut mood and performance, and the impact on humans confined to small quarters and remote locations. Also reported to be in the offing is a review of past work in the behavioral

sciences, in order to identify research gaps and plan the steps that should be taken next.

The Soviets have been deeply interested in the psychological aspects of space flight since the inception of their program, and they have a strong and vigorous approach to this facet of spaceflight. In fact, the Soviets state quite clearly that long-term spaceflight is highly dependent on the psychological state of the crew, and that they are taking every possible measure to ensure a good mental state in their cosmonauts. They engage in research, testing, training, in-flight observation and troubleshooting, and postflight evaluations.

The Group for Psychological Support does much of this work, and it is supported by programs under the head of crew training, General G. Beregovoi. For example, the group is constantly performing sophisticated voice-stress analysis while the crew is in space. When high levels of stress are indicated, or are growing, the group arranges interactive television meetings with family, friends, famous people, and the scientists involved in the experiments the crew is conducting. They have arranged for surprise packages to be delivered in the Progress resupply ship in addition to special foods, fresh fruit, letters, video movies and special programs, gifts, and even a guitar. One goal of the Intercosmos program, which has brought cosmonauts from many non-Soviet countries to spend time at the space station, has been to break the boredom, monotony, and loneliness of crews on very long missions, not just meet the technical goals. "Parties" are planned with ritual salt and bread, the customary foods of the visitor's country, and so on. The Salyut-7 spacecraft, moreover, included changes in color scheme and design to make life on board more pleasant. Under General Beregovoi, all cosmonauts go through a rigorous training program intended to develop self-reliance, self-control, self-confidence, and the ability to keep calm and alert in an emergency.

Despite all of these efforts, however, the Soviets still report problems. They state publicly that they have not developed adequate methods for establishing compatibility between crew members and that much is still done on a commonsensical level. The Soviets are also showing serious interest in the relationship between the biological effects of weightlessness and the potential impact on moods, attention, and motivation.

The overall Soviet approach seems to be one of providing the crew with a variety of possible alternatives—skills, knowledge, and psychological training—for coping with long-term space sojourns. The Soviets assume that man is not limitless in his capacity to adapt, and that success demands a good understanding of strengths, weaknesses, and boundaries so that man and environment can work synergistically. To leave the human element—one of the most important factors in the "loop"—to chance or "common sense" seems to them to be an unscientific approach.

It is very difficult, I should note, to evaluate Soviet materials, even when they are available. The Soviets have a different approach to the treatment of data then those trained in the West; thus, they do not include information that might be thought necessary from our point of view. What is seen, however, seems to be heavily oriented to the biological and psychological questions, with little emphasis on social systems. Cosmonauts seem to be looked at from the psychological perspective and not as members of a complex system of social layers and group dynamics. Again, though, this may not be the case. The Soviets claimed quite vigorously that they were not planning to send any more women into space for quite a long time and for many reasons—but then Svetlana Savitskaya was placed aboard the Salyut 7 in August 1982.

Spaceflight experience (especially by the Soviets on very long missions), together with data from isolated, confined, and stressed populations, shows that the longer a flight, the more critical social and psychological factors become to flight safety and mission effectiveness. This experience also shows the importance of the human factor in space. As spaceflights continue, the involvement of practical behavioral sciences will no doubt increase, giving rise to unprecedented opportunities for applications and research. Space stations are natural laboratories. Situations are real, yet groups are small, making it possible to manage the information. Crews may be willing to try different social systems and thus provide an opportunity—in isolation from the interfering variables that plague earth-based research—to learn a lot about fundamental social processes. The frontiers of space are also the frontiers of social science.□

Little Green Men and All That

Ron Westrum, David Swift, and David Stupple

The idea of a plurality of inhabited worlds is indeed an old one, having inspired and troubled man since ancient times. Whether man is alone in the universe, whether there are other worlds with intelligent beings on them, possibly superior to us in knowledge, are questions that have long exercised our reason and our imagination. With the development of modern space technology and radio astronomy, we have taken the first steps to explore nearby worlds directly and to scan far-off ones for signals from intelligent life. Our civilization is now at the stage where we have not only evolved sophisticated ways for thinking about extraterrestrial intelligence (ETI), but have also developed means for detecting and communicating with such intelligence. Yet the technical feasibility of detection and contact must confront questions of broader social policy. How much money is to be spent on such searches? Who will be responsible for carrying them out? What kind of searches should be carried out? To date, no searches for electromagnetic signals have been positive. Are further searches worthwhile? What kind of attention, if any, should be given to investigating UFO sightings, whose reported strangeness would seem to suggest extraterrestrial origins?

Whatever decisions we as a society make on these issues in the long run, the concept of ETI is affecting our society in many ways—through science fiction books, films, and television programs; with respect to our religious beliefs; through public interest in the space program; and in regard to our self-image as unique beings in the universe. Our children play with toy rocket ships and models of E.T. This response to the idea of ETI strongly reflects the hopes and fears of our society about its own future welfare.

Our purpose here is to examine American society's response to the ETI concept. To do so we have chosen three subcultures in American society whose existence is based on the idea of extraterrestrial contact. The first subculture consists of *religious groups* which believe that contact is now taking place and that messages from "space brothers" have already been given to human beings. The second is made up of groups and individuals who investigate UFO sightings, the "*UFOlogists*." The third subculture consists of *scientists* who are actively involved with research and thinking about intercepting signals from extraterrestrial intelligent species. Each of these subcultures believes that ETI exists and that it is making active efforts to contact us. Apart from this assumption, though, the membership, social structure, norms, and intellectual underpinnings of these groups are quite different. Each tends to regard the others with indifference or even scorn, in part because of differences in style, methods, and membership, but also because they represent three competing responses to the same basic idea.

If there are people on other planets, then why can't they come here? And if they do come here, then why don't they land on the White House lawn? Might they pick a humble person to communicate with? After all, didn't God pick Jonah to deliver one of his messages?

This basic premise, that extraterrestrials could arrive on earth and communicate with ordinary people, underlies the entire "contactee" subculture we are about to examine. It provides a rationale for individuals who have had "contacts" to speak publicly about their experiences, for others to elaborate doctrines based on such experiences, and for the formation of organizations to collect and disseminate such testimonies and doctrines. The inherent interest in such testimonies (if true) and the vividness with which they are related also allow for their exploitation by the mass media—particularly by radio

and television talk shows. No matter how implausible the basic premise might seem to others, there is no question that, for millions of Americans, this premise not only made sense but seemed to have been proved correct by the testimonies contactees gave about their meetings with the "Martians," "Venusians," or whatever. Today, there are hundreds of small religious groups in the United States which believe that extraterrestrials are in contact with earthlings and that they wish to help us.

> If there are people on other planets, some say, then why can't they come here. And if they do come here, then why don't they land on the White House lawn?

George Adamski was the first of the contactees. In 1952, at age 61, Adamski claimed that he had a meeting with Orthon, a man from Venus, near Desert Center, California. Before his experience, Adamski had been a handyman and an undistinguished teacher of "metaphysics." He was also interested in photography and had previously produced pictures of UFOs, later labeled fraudulent by the Air Force. In 1953, in a book published with the British writer Desmond Leslie, *Flying Saucers Have Landed*, Adamski gave the first of many accounts that he and others were to offer of meetings with extraterrestrials. Other contactees, among them Truman Bethurum, Orfeo Angelucci, Howard Menger, and Daniel Fry, rapidly gave their own accounts of such meetings and of the behavior and message of the "space brothers." How sincere they were is open to question. Adamski, Menger, and Fry were caught in falsehoods, and others were very suspect, but their "messages" had effect.

The contactees were a predictable attraction for radio and television talk shows; Long John Nebel, Betty White, and Steve Allen all featured them. The 1950s were a time when the threat of atomic war seemed very real. For many people, it must have been comforting to believe that benevolent intelligences from other planets were watching over them and that they were communicating messages of warning and hope to earthlings who would then pass them on. Furthermore, such accounts were intrinsically exciting, if improbable. The media found in the contactees an easy way to exploit the high public interest in flying saucers. The contactees themselves basked in the attention, and proceeded to translate it into invitations to speak at "platform societies" and to found their own "flying saucer clubs."

Platform societies sponsor a succession of speakers on topics relating to psychic abilities, religion, spiritual healing, mysticism, and similar matters. Such groups sometimes sponsor psychic fairs, where local practitioners exhibit their skills in astrology, tarot reading, and various practical parapsychologies. They also may offer courses in the "mystic arts." The members of platform societies, contrary to an influential study published in 1966 in this magazine, are *not* society's marginals, the elderly, infirm or unadjusted who "cannot carry on a conversation." Religious scholar J. Gordon Melton, familiar with many of these groups, suggests that their members are "ordinary people with some extraordinary beliefs." Although many of them are well educated, they tend to be uncritical. They accept each speaker as having, in their words, "part of the truth." In Detroit, a common metaphor compares rival esoteric systems to looking at a house through different windows; each has its own view of the same room. The contactees, whose stories of exotic contacts with "space brothers" fit easily into the framework of these groups, became popular speakers for them. The attention they received, moreover, allowed the contactees to develop their own groups, and many of their disciples learned useful organizational techniques from participation in the platform societies.

From about 1954 to 1959, the flying saucer clubs became a major vehicle for the organization of people interested in the religious aspect of extraterrestrial contacts, and they were reinforced by a succession of newsletters, magazines, and articles devoted to flying saucers and their ostensible occupants. By the late fifties, the contactees' popularity was eclipsed by the growth of the publishing industry which had developed to promote them and the idea of flying saucers. *Fate*, a popular magazine devoted to the occult, found that publishing flying saucer stories helped its circulation immensely. One of its editors, Ray Palmer, left *Fate* and founded his own magazine, *Flying Saucers*, which was strongly dependent on the contactee and "UFOlogy" subcultures. Another publisher, Gray Barker, got his start in the business through a "creature story" published in *Fate*, and he went on to write *They Knew Too Much about Flying Saucers* (1956), the book that first described the "three men in black" who threatened witnesses. The men in black were to become a staple item of UFO lore. Barker eventually set up the Saucerian Press, which continues to publish books oriented to contactees and the more exotic aspects of UFO folklore. Barker's mailing list now includes 4,500 names, mostly people oriented to contactee themes rather than to occult or metaphysical ones, according to evidence from a reader poll. As the popularity of the better known contactees waned, these publishers became celebrities themselves, often in demand on the lecture and convention circuit.

But the 1960s witnessed the decline of the flying saucer clubs and the fragmentation of the contactee subculture into a large number of only loosely related segments. The most easily identifiable groups are relatively large and organized charismatic congregations, such as

George King's Aetherius Society, and are dependent on a single figure for leadership and prophetic messages. The Aetherius Society has perhaps 1,500 members in the United States and England. On a similar scale are psychic groups, such as Ruth Norman's Unarius Foundation in California, that often have substantial mailing lists and for which extraterrestrial contact is an important topic of interest. Nonetheless, there is a larger number of small groups whose members are also interested in hearing about messages from space. These include the platform societies as well as smaller groups organized for discussion, reading, and sometimes projects related to contact ideas. One such group was building a large "flying saucer" that, it was believed, would one day fly. Several highly skilled members of the group worked on making the vehicle structurally sound (the propulsion unit was to be supplied by the extraterrestrials). The group seemed to exhibit a working-class culture of recreational excitement, and much of the group's attention was focused on the physical task of getting the saucer built.

These diverse contactee groups also share several literatures, including books on contact experiences, astrology, psychic science, "metaphysics," nontraditional healing, and various forms of self-help. Much of the contactee literature has a "new age" emphasis, in many ways paralleling the Age of Aquarius theme in the youth movements of the 1960s. Much of it contains a millennial message suggesting that the space brothers are soon going to intervene and help mankind in various ways. Much of it, in other words, contains "good news for Spaceship Earth" from the extraterrestrials, who are usually described as wise and benevolent. The literature also contains a contactee folklore, mostly manufactured by the writers and publishers. The literature, its personalities, and its folklore provides the thread that ties together (very loosely) the contactee subculture.

Today there are hundreds of small religious groups in the United States which believe that extraterrestrials are in contact with earthlings.

In sum, the contactee subculture, born in the 1950s, is now maintained through an extremely diverse set of groups, some of which are organized as religious sects or as contactee cult groups. Others are set up as study groups or around a project, such as the saucer-building group mentioned above. These groups borrow skills and ideas from nontraditional religious systems (such as theosophy) as well as from psychic societies; they also draw upon UFOlogy, though to a lesser extent than one might expect. The members of these groups are largely working class or lower middle class and tend to have a lower educational level than UFOlogists, to whom we will next turn our attention. The religious needs to which these groups appeal and the opportunity for sociation in the doctrinally tolerant context they provide will probably make the contactee subculture viable for many years to come.

Collective Behavior or Protoscience?

UFO sightings, and those who investigate them, can be viewed in either of two very different ways. On one hand, the phenomenon might be seen as an example of collective behavior and the contagion of perceptual experiences, and one might seek the supposed "structural strains" that led to the outbreak of such experiences in American society. Or it might be seen as the courageous struggle of inquisitive amateurs to bring to light events that the scientific community would just as soon ignore. Both views have some substance, and both can be supported by emphasis on one or another portion of the social behavior exhibited by sighters, investigators, the mass media, the military, and the scientific community (to name only a few of the actors involved). The treatment of UFO experiences by American society is complex, and here we can only sketch its outlines.

While experiences that might be labeled "UFO" go far back in history, the concept "flying saucer" was first applied to an actual experience in June 1947, after a spectacular sighting near Mount Rainier led to extensive newspaper coverage. Within weeks, hundreds of sightings had been reported in newspapers all over the United States. One sociologist, Herbert Blackett, was convinced that the flying saucer "craze" was "almost wholly a manufactured concept" and that it would quickly disappear. This expectation, however, was incorrect. The vividness and popularity of the "flying saucer" (a.k.a. "unidentified flying object") concept meant that it could and would be applied to a large number of aerial objects—some of them, to be sure, identifiable enough. In the 1960s, public opinion polls showed that about one in twenty adults felt that he/she had seen a UFO; by the 1970s, this figure had risen to one in ten. Not only did UFO sightings not go away, they continued in full force, although their apparent extent has varied with shifting media coverage.

Interestingly enough, UFO sighters are roughly a cross section of the American population. They are not distinguished from nonsighters by income, education, race, sex, or religion. Although one study did suggest that some of them might be status-inconsistents, a follow-up study did not support this hypothesis. There is, however, one factor that is consistently related to UFO sightings, and that is youthfulness. The data show that the younger one is, the more likely one will report having sighted a UFO. While the meaning of this finding is not clear (it may have to do with differential willingness to label a perception a "UFO"), it suggests that there is some re-

lationship between social structure and UFO observations. That there is, also, a strong predisposition for people to perceive UFOs, as indicated by the ability of UFOlogists to identify about 90 percent of reported sightings as known objects. UFOs, then, are part of our culture—and of the cultures of other nations, as well, since UFO sightings are a worldwide phenomenon.

The intense interest that UFO sightings evoke, of course, has to do with the possibility that some of the observed objects might be extraterrestrial vehicles. This possibility, and others, led to the early investigation of sightings by the American armed services, notably the U.S. Air Force. In the twenty-year period that the Air Force was publicly involved in the investigation of UFO sightings, it would sponsor two major studies—one by the Battelle Memorial Institute, the other by the University of Colorado. The overall conclusion of both studies was that UFOs did not provide evidence of extraterrestrial visitation, although the data were actually far from unequivocal. In both cases, there is some evidence of analysis being slanted to please the sponsors of the research. The Air Force's own UFO investigation unit, variously called Sign, Grudge, and Bluebook (reflecting its shifting orientation), was under even more pressure to come up with negative conclusions, and usually did.

Continuing publicity given to UFO sightings by the mass media, magazines, and books made some of the public impatient with Air Force investigations, which seemed slow, uninspired, and perhaps dishonest. The latter impression was reinforced by the books of a retired Marine Corps major, Donald Keyhoe, who used contacts inside the Air Force to find out "what was really going on." The combination of curiosity and frustration led civilians to found their own organizations to investigate sightings. The Aerial Phenomena Research Organization (APRO) and Civilian Saucer Intelligence (CSI) were formed in 1952; and the organization destined to become the largest, the National Investigations Committee on Aerial Phenomenon (NICAP), was created by Keyhoe and others in 1956. At its peak, the now defunct NICAP had 10,000 members and published several large compilations of information on sightings. The largest and most active organization currently is the Mutual UFO Network (MUFON), which has about 1,500 members and an investigator network covering the United States. MUFON's annual conventions bring together many of the intellectual leaders of the UFO movement.

UFO-investigation organizations display many of the usual problems of voluntary associations. Success is often dependent on leadership; finances are a recurrent problem; ensuring membership participation and conformity requires strenuous effort; and factions are common. The organizations would like to present their work as scientific, but scientists are a tiny minority among UFOlogists. Typical of the problems faced is the constant struggle to get members to submit investigation reports on standardized forms, or to submit any reports at all. In spite of these difficulties, a fairly large volume of investigation (of varying quality) does get carried out, and many of the more interesting reports are published in UFO periodicals, conference reports, and books.

What is the nature of the knowledge so developed, and what is its value? This is very difficult to assess. Investigation of UFO sightings is carried out ordinarily as a hobby in one's spare time, on weekends, evenings, or on time bootlegged from one's job. The cost of investigating an interesting case probably approximates that of a difficult homicide investigation; the time and money for a thorough job are seldom available. The number of interesting cases of close encounters, landings, physical-trace cases, sightings of "humanoids," even "abductions" in the literature is quite large. It is as difficult for most insiders *not* to believe that something unusual is taking place as it is for outsiders to believe something is. Certainly the extent and strangeness of the reported events seem to call for continuing inquiry. Nor is it correct to believe that when scientific investigators look at the same cases, they find nothing. Both the Battelle Memorial Institute study and the University of Colorado study (popularly known as the Condon Report) had a large fraction of unexplained cases from "reliable witnesses."

Continuing publicity given to UFO sightings made some of the public impatient with the Air Force investigations which seemed slow, uninspired, and perhaps dishonest.

UFOs have not been entirely ignored by other scientists. In 1953, Donald Menzel, a distinguished astrophysicist at Harvard, published *Flying Saucers*, a substantial book whose thesis was that sightings are largely attributable to aerial mirages. Although his specific optical explanations were later discounted, Menzel's authority was probably quite influential in persuading his colleagues not to take UFOs too seriously. (Menzel's coauthored second and third books appeared in 1963 and 1977.) In 1965, a different approach was taken by the astrophysicist and computer scientist Jacques Vallee, whose *Anatomy of a Phenomenon* turned Menzel on his head. Menzel had argued that people were good at seeing what was not there; Vallee argued that society was good at not seeing what was there, and that the UFO reports and science's response to them were well within the parameters for a real extraterrestrial visitation. Vallee's thesis received additional support in 1972 with the publication of J. Allen Hynek's *UFO Experience*.

Hynek's book was the first truly scientific examination of the UFO phenomenon. At the time, Hynek was chairman of the Department of Astronomy at Northwest-

ern University, and he had served for many years as the major Air Force consultant on UFOs, a position that won him little sympathy from UFO advocates. His "swamp gas" explanation of the 1966 Michigan sightings had become a national joke. Yet, his book was remarkable in two respects. First, unlike the books of Menzel and Vallee, it was based almost entirely on his own field research. The others had relied largely on secondary accounts—some of which were later shown to be fraudulent—and theoretical arguments. Second, it suggested a classification of UFO phenomena that is still widely used by UFO investigators and enthusiasts and that permitted a specialization which characterizes much contemporary UFO investigation. Hynek's books were eventually followed by other scientifically oriented works, and his Center for UFO Studies in Evanston, Illinois, carried out investigations leading to Allen Hendry's *UFO Handbook*, a comprehensive analysis of 1,307 UFO cases, of which 9 percent remained unidentified after investigation.

Doubters of the reality of UFO sightings have also been active, principally in the person of Philip J. Klass, a senior editor of *Aviation Week*, whose book (in 1968) suggested that UFO sightings were attributable to ball lightning. His next books, in 1974 and 1983, concentrated more on the possibilities of optical illusion and fraud. Energetic, inquisitive, and somewhat ruthless, Klass came to provide a constant counterpoint to proponents' claims that this or that sighting was unexplainable. He was joined by James Oberg and Robert Sheaffer, both of whom later wrote their own debunking books on UFOs. Oberg, like Klass, is a science writer; Sheaffer is an engineer. All three are members of the Committee for the Scientific Investigation of Claims of the Paranormal (CSICOP), an organization set up to debunk paranormal beliefs. The critics focus on the weak points in the proponents' arguments, reinvestigate in some cases, and criticize them in the mass media. In recent years, there have been many heated exchanges between proponents and critics, in print and in person, but with little resolution of basic differences.

The UFO investigation community, then, consists of a large number of interested amateurs, a small number of scientists, and a handful of active critics. This community has developed its own literature, its own folkways, its own jargon, and its own knowledge base. Not all UFOlogists feel that the evidence points to extraterrestrial visitation. But most believe that something very much out of the ordinary is taking place. One day, perhaps, UFOlogy will be placed alongside phrenology as a deviant and unsuccessful paradigm. Its practitioners, however, see themselves as pioneers in the recognition of the first manifestations of a nonhuman intelligence.

Is Anyone Out There Sending?

While UFOlogists are looking for extraterrestrials in the atmosphere, another group is seeking evidence in the form of electromagnetic signals from distant stars. Members of this group, the SETI (search for extraterrestrial intelligence) community, are almost all scientists who tend to think that telepathy or flying saucers are irrelevant to ETI contacts. If such contacts are to be made, some form of electromagnetic energy—radio, light, etc.—is the likely channel. This group's attention, theoretical effort, and attempts to obtain funding thus center around the means for detecting such signals. The members of the SETI community (most visibly represented by astronomer Carl Sagan) are largely astronomers, engineers, astrophysicists, and biologists who share a common framework for discourse, although they often differ on the "realistic" estimates for the quantities which interest them. The majority, however, think that intelligent life elsewhere in the universe is very probable, if not certain.

While the notion of intelligent life on other worlds goes back to ancient times, the SETI movement is barely a quarter of a century old. Its beginning might be traced to a 1959 article, published by physicists Giuseppi Cocconi and Philip Morrison in the respected British journal *Nature*, that attracted wide attention. The next year, Cornell astronomer Frank Drake conducted OZMA, the first search for extraterrestrial radio signals. And in 1961, at a meeting convened by the National Academy of Sciences at Green Bank, West Virginia, the movement crystallized. During that meeting, one of the eleven participants, Melvin Calvin of Berkeley, was notified that he had won a Nobel Prize; this incident is indicative of the status of many members of the SETI community. Most are PhDs at leading universities or prestigious research institutions. Four members of the Green Bank group have continued to work on SETI: Morrison at MIT, Drake at Cornell, Carl Sagan (also at Cornell), and engineer Bernard Oliver, who is vice-president for research at Hewlett-Packard. Another central figure in SETI research is the British physician John Billingham, now chief of the Extraterrestrial Research Division at NASA's Ames Research Center in California.

Since this group has strongly influenced intellectual discussion and research efforts, its basic assumptions are worth considering:

- First, the development of life is a natural process—merely a matter of probability, not a miracle requiring divine intervention. Thus, given the enormous number of stars likely to possess planets, the chances are extremely high that life has originated not once, but many times.
- Second, the development of intelligent life is also a matter of probability and is also to be regarded as a natural process. There are differences regarding how intelligent life is likely to develop and how closely it is likely to resemble Homo sapiens. George Gaylord Simpson, an authority on evolution, considers the chance of anything resembling man in intellectual capacity to be vanishingly small. Others, such as Carl Sagan and Frank Drake, are much more optimistic.
- Third, these civilizations are likely to carry on com-

munications with the planets of other stars not by means of spacecraft but, rather, through the medium of electromagnetic signals. The distances between inhabited planets are simply too great to make interstellar travel common or even feasible.

- Finally, since the distances are so great, the time required even for radio signals must make two-way communication a very long process. It would take eight years for a single message and reply between earth and the nearest star system. Thus, it is simpler and cheaper to begin by trying to detect others' signals. If these attempts succeed, then we can consider sending replies. To send messages, now, however, without knowing where to send them, would be a waste of scarce resources. Thus contemporary American efforts focus on SETI, searching for ETI, rather than CETI, communicating with ETI.

There have been twenty-two searches for such signals, none successful. This lack of success is not surprising. The searches have sampled only an infinitesimal fraction of the sky and have used only a very narrow range of radio frequencies. As assumptions about what to look for and where to look change, and as the technology of search instruments steadily improves, there are likely to be many more searches.

SETI faces three obstacles: funds, competition for search frequencies with other users, and opposition within the scientific community. Funds are a serious problem for SETI. All the searches thus far have been conducted with small budgets and rather primitive data-processing equipment, and they have been able to cover only a small portion of the sky. One 1971 design, Project Cyclops, called for a system that would have cost perhaps $20 billion, but funding at this level is unthinkable. The current, far more modest system, which concentrates on signal processing rather than on reception capabilities, was designed to require a startup cost of $2 million for 1982. Initially, Congress turned the request down, but in 1982 it did budget $1.5 million for 1983. These funds were to cover only the first five years of R&D on a multichannel spectrum analyser, to be conducted by Stanford University in cooperation with the Jet Propulsion Laboratory. The system will be able to process 74,000 channels simultaneously, once developed. Five years will be spent on the actual search.

Another problem is that the frequencies desired by SETI investigators are also being sought for more mundane uses. For instance, the 1400-to-1727-megahertz band—thought to be an obvious "window" for interstellar communication—is also used for mobile communications, satellites, and radiosondes on weather balloons. While SETI investigators want these frequencies to be kept open for ETI searches, other interest groups have their own agendas. Furthermore, use of the radio spectrum is an international matter, and agreements have to be negotiated through the World Administrative Radio Conference, which includes 150 nations.

Still another problem is that more than one view exists in the SETI community. A strong minority position, first articulated by Michael Hart of Trinity College, Texas, holds that humans may well be the only intelligent life in the universe. Hart's view also differs from the majority in that he thinks space travel is not only a possibility, but a certainty, with technically advanced civilizations. If there were ETI, its presence would be manifest on earth; since there are no ETIs on earth there is no ETI. Other "pessimists," less willing to concede the feasibility of space travel, take issue with other tenets of the majority view, such as the likelihood of other planets that support life. The creation of intelligent life on earth required, it is suggested, so many "lucky accidents" that one can regard it almost as a miracle. These and similar concerns were instrumental in bringing the minority together for the first "we are all alone" conference in 1979. While this minority is still small, its influence and power are growing. Once the majority view was so strong that it was difficult for the pessimists even to publish papers in the more established journals. Now this trend is gradually being reversed.

Although their work and thinking have been highly publicized, the number of scientists directly involved with SETI is quite small. Few, if any, scientists devote all their time to it. Probably fewer than a dozen give most of their energies to projects specifically dedicted to SETI work; probably fewer than a hundred scientists are working in areas closely related to SETI. Although a majority of Americans believe that there is intelligent life elsewhere in the universe, they have devoted relatively few resources to searching for it.

Whereas Donald Menzel had argued that people were good at seeing what was not there, Jacques Vallee argued that society was good at not seeing what *was* there.

Two factors account for this limited activity. First, many of the researchers active in SETI are also busy in other, more conventional research activities. Since the chances that any one individual will make a major discovery in SETI appear so slight at this time, the ambitious scientist is reluctant to divert much energy away from other activities having a higher probability of success. Second, it is very difficult to get funding for SETI research. Contrary to a prevalent misconception, SETI funding from the National Science Foundation and NASA has ranged from nonexistent to nominal. Even in its more prosperous years, the SETI unit in NASA had only one or two scientists and a small secretarial staff.

Thus, although well trained and influential, the active

SETI community is relatively small. Though its funding is modest, its prestige and access to the instrumentation and talent of neighboring specialties have allowed it both to carry out research and to publicize its activities. The impact of this group on our society testifies to its intellectual power.

Signals and Noise

In a 1977 report prepared for the U.S. House Committee on Science and Technology on the subject of ETI, one can find this interesting sentence: "Many supporters of the thesis that there are other intelligent civilizations do not support the contention that they have visited Earth—UFOs are not discussed in this report." This remark, which expresses widespread and quite strong sentiments in the SETI community, points to a striking division between UFOlogy and SETI, two human enterprises that otherwise might be seen as closely connected. Both, after all, presume highly advanced extraterrestrial civilizations as well as efforts by those civilizations to communicate with others. Obviously, such civilizations might choose more than one means of exploration or communication, and it would seem difficult a priori to determine the most likely means. Both subcultures have the problems of separating "signal" and "noise" in regard to data. Yet the prestige of these two fields of endeavor could hardly be more different, nor their participants more strongly opposed to each other's views. For all intents and purposes, these two research efforts might as well be taking place in different countries, since they appear so far apart intellectually.

This gap between the two subcultures shows up in several ways. Most conspicuous is the lack of citation of each other's work in publications. Although the work of the two groups would seem complementary—after all, they are exploring different aspects of the same problem—such complementarity is not acknowledged by either side. Similarly, those who attend the meetings, conventions, and briefings of one subculture seldom appear at those of the other. Finally, there are occasions when one subculture publicly attacks the other. One instance was a program in the *Cosmos* television series, narrated by Carl Sagan. In the program, Sagan's treatment of UFOlogy was largely negative; and since the series received enormous popular attention, it is to be presumed that his views were quite influential. Similarly a *Nova* program on UFOs was co-opted by the UFO critics, whose views were not only more frequently quoted, but were also given more sympathetic treatment. It might be that the tendency of the news media to find an "angle" for a given program makes them tilt more toward one side or the other, rather than present a balanced approach.

But there are rare occasions when the gap is bridged. Carl Sagan and Frank Drake were responsible for a panel on UFOs at the 1969 meetings of the American Association for the Advancement of Science. The participants included proponents, critics, and neutrals; the selection of speakers and topics was remarkably evenhanded. Sagan had also participated in the 1968 hearings before the House Committee on Science and Astronautics which dealt with UFOs, even though most of the speakers presented pro-UFO statements. Yet, despite these contacts, neither subculture appears to have had any real impact on the other. We are left, then, with a need to explain this phenomenon.

The first major cause of the separation lies in the histories of the two subcultures. UFOlogy was begun by amateurs and remains largely an amateur pursuit; this is reflected in its conferences and publications, and in the quality of the typical UFO investigation. The scientists and engineers who participate in UFOlogy have been for the most part recruited by the amateurs, and often have joined them only reluctantly. UFOlogy, furthermore, has a lunatic fringe from which it has been unable to disassociate itself. Although some UFO organizations, like NICAP, have tried to develop strict rules for what will be admitted as genuine UFO cases, the ambiguity of the data has not permitted these boundaries to be shared universally among influential UFOlogists. If one cannot definitively determine what is a UFO and what is not, cloture is very difficult. One might call UFOlogy an "incomplete paradigm." Furthermore, the realities of the lecture circuit and the media have often tempted "serious" UFOlogists to share the spotlight or the rostrum with other groups whose views they do not completely accept. The net result is that there is no well-demarcated "amateur" subculture that can be co-opted by the broad scientific community, let alone by SETI.

"UFOlogy" has a lunatic fringe from which it has not been able to disassociate itself.

The SETI community, on the other hand, began and remains an "invisible college" within the scientific community, and the chosen technology—electromagnetic receivers—simply does not permit amateur participation. Many of its members are scientists of considerable prestige, and even those who disagree with the majority position accept the conventions and folkways of the scientific community. The intellectual weight that can be brought to bear in favor of SETI is truly impressive. In 1982, Carl Sagan organized a petition with sixty-eight other signatories in favor of an international SETI project. The list reads like a "Who's Who" in astronomy, physics, and biology. Seven Nobel prize-winners are included. Thus, unlike the UFOlogists, whose social situation often dictates uneasy alliances, the

SETI investigators have no need for compromising ties. There is, however, one tie of dependence which is important, and that is to the organs of funding. The legitimacy and the funding of SETI research is tied to its position within the scientific community, and to the prestige of its members.

This leads us to the second major reason for the gap. Not only is UFOlogy a potential contender for government funds, but any association between UFOlogy and SETI would have negative implications for SETI funding. The potential threat of such an association is that the ridicule often attaching to UFOlogy might spread to SETI research. Given the current congressional attitude that SETI research is questionable anyway, an association with UFOlogy might burden it with an unshakeable albatross. (Conversely, it would provide UFOlogy with some very prestigious defenders.)

> The ways in which humans have responded to the concept of extraterrestrial intelligence reveal a good deal about who *we* are.

One incident nicely illustrates the dangers to SETI of UFOlogical involvement. One participant in the 1971 debate over the supersonic transport (SST) before the U.S. House of Representatives was the distinguished meteorologist James McDonald. When McDonald gave testimony as to what he believed the effect of the SST on the atmosphere would be, his views on UFOs were brought up in order to ridicule him and discredit his testimony. He was actually laughed at during the hearing. One congressman suggested that "a man who comes here and tells me that the SST flying in the stratosphere is going to cause thousands of skin cancers has to back up this theory that there are little men flying around in the sky. I think this is very important." It does not require much imagination to anticipate how a similar association between SETI and UFOs might affect the funding chances of the former. After criticism of the current SETI microwave program appeared in *Science* magazine, one of the program's originator's felt it necessary to assert that SETI "is now, and has been for decades, a scientific endeavor." Hence, whatever the private views of SETI investigators about UFOs, it is in their interest to maintain a complete dissociation in public. Since even the UFOlogist's existence is seldom acknowledged by SETI investigators, the UFOlogists, too, have reason for maintaining the separation. Why should they try to approach those who so strongly reject them?

The gap between the two subcultures, then, ostensibly an intellectual question ("the UFO evidence is just too weak"), is exacerbated by a conflict of intellectual styles and a struggle for legitimacy and funding. It is evident that some of the intellectual bases for disagreement ("the stars are too far away") between SETI investigators and UFOlogists are questioned even by some of the former (for instance, Michael Hart). Both, furthermore, can always come up with new projects: a single ETI signal or a single proved UFO case would instantly propel either activity into priority status, but to prove that there are *no* UFOs or ETIs is difficult, if not impossible. It is not impossible, then, that the two subcultures will continue to work in virtual isolation from each other.

We have seen in these three subcultures three distinct responses to the concept of extraterrestrial intelligence. In each case, the talent, resources, and folkways of the subculture have contributed to shaping intellectual orientations and activities. Just as it seems perfectly logical in the contactee subculture to search for quasi-religious messages from "space brothers," it seems logical to UFOlogists to interview witnesses of strange aerial objects, and logical to SETI investigators to look for electromagnetic signals from distant planetary systems. Each of these responses shows a human attempt to reach out, to understand, and to grapple with the possibility that we are not alone in the universe. Each betrays the hopes, fears, beliefs, and abilities of the people involved. In contemplating the consequences of actual contact, it might be well to try to understand the inner spirit of each of these endeavors, since they reveal a good deal about who *we* are.□

II. SPACE LAW

COMMERCIAL SPACE ACTIVITIES UNDER THE MOON TREATY*

Martin Menter**

I. INTRODUCTION

The Moon Treaty, on adoption, will establish the principle that the moon and its natural resources are the common heritage of mankind. The establishment of an international regime is contemplated to govern exploitation of such resources with "equitable sharing" by all States in the benefits derived from those resources, with "special consideration" for developing countries and countries contributing to the exploitation. This paper examines the apprehension of private enterprise to invest funds in a moon activity requiring sharing of profits with States that had not shared in the risks involved. In light of the Treaty's negotiated history, conclusions made are that the nature of the sharing has not yet been determined; that such must await a subsequent separate treaty negotiation for the governing international regime when exploitation "is about to become feasible," an eventuality perhaps thirty or more years from now; that in the interim, there is no moratorium on exploitation and States may authorize their governmental and nongovernmental entities to undertake exploitation of the moon's resources. Private sector planning for and investment in commercial space activities, with Government support, is encouraged.

II. INTERNATIONAL COOPERATION IN SPACE ACTIVITIES

A. The Space Law Treaties

The Agreement Governing the Activities of States on the Moon and Other Celestial Bodies (TOM), on December 5, 1979, was recommended by resolution of the United Nations General

Assembly for signature and ratification.[1] Like its three predecessor treaties formulated by the Legal Subcommittee of the United Nations Committee on the Peaceful Uses of Outer Space (COPUOS) since adoption in 1967 of the Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies[2] (OST), the TOM is an expansion of principles embraced in the basic OST governing space activity. The TOM carries forward the OST objectives of international cooperation in space activities, with all nations to share in the benefits of space exploration without regard to their level of economic or scientific development.[3]

B. Freedom from Sovereignty

The appeal of the OST for international accord in exploration and use by all States was strengthened by the omission of the historical concept applicable to discovery and exploration of land masses on Earth, viz: the obtaining of sovereignty upon "effective occupation" over a *terra nullius*. In lieu thereof, the OST proclaimed, "Outer space, including the moon and other celestial bodies, is not subject to national appropriation by claim of sovereignty, by means of use, or occupation or by any other means."[4] Without this provision, States which established settlements on celestial bodies or otherwise in space might well be reluctant to then surrender

2. Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies, *done* Jan. 27, 1967, 18 U.S.T. 2410, T.I.A.S. No. 6347, 610 U.N.T.S. 205 (*effective* Oct. 10, 1967) [popularly known as the "1967 Treaty on Outer Space," hereinafter cited as OST]. The three interim predecessor treaties were: Agreement on the Rescue of Astronauts, the Return of Astronauts and the Return of Objects Launched into Outer Space, *done* Apr. 22, 1968, 19 U.S.T. 7570, T.I.A.S. No. 6599, 672 U.N.T.S. 119 (*effective* Dec. 5, 1968); Convention on International Liability for Damage Caused by Space Objects, *done* March 29, 1972, 24 U.S.T. 2389, T.I.A.S. No. 7762 (*effective* Oct. 9, 1973); Convention on Registration of Objects Launched into Outer Space, *done* Jan. 14, 1975, 28 U.S.T. 695, T.I.A.S. No. 8480, (*effective* Sept. 15, 1976).

3. See OST, *supra* note 2, at Preamble, art. I; TOM, *supra* note 1, at Preamble, arts. 2, 4.

4. OST, note 2 *supra*, at art. II. For a discussion of application of prior principles to space discovery and settlement in the absence of an international accord precluding vesting of sovereignty, *see* M. Menter, Jurisdiction Over Land Masses in Space, address at the American Rocket Society Space Law and Sociology Conference, Carnegie Endowment for International Peace Building, New York City (Apr. 24, 1962).

whatever inchoate sovereignty rights accrued by such settlements. Many an armed conflict emanated from conflicting sovereignty claims on Earth; this possibility in space was to be avoided. The time to resolve this foreseeable problem was before such space exploration and settlement could occur.

The TOM contains a similar recital against national appropriation of the moon.[5] While some writers and States had contended that the OST Article II prohibition would preclude exploitation of the moon's natural resources, the prevailing view appears to permit such exploitation.[6] It is believed that the intent of this provision was to preclude application of the historical concept of sovereignty attaching to exploration and establishment of dominion over newly discovered portions of the Earth.

III. THE PRIVATE SECTOR IN SPACE

A. Space Communications

Private sector commercial space activities by U. S. companies followed the enactment by the U. S. Congress of the Communication Satellite Act of 1962.[7] The act established the Communications Satellite Corporation (COMSAT) which was authorized to create and operate, or in conjunction with foreign governments or business entities to operate "a commercial communications satellite system."[8]

B. Remote Sensing

Private sector ownership and management of a civil operational land remote sensing activity is currently being studied by the U. S. Government. Planning and development responsibilities therefor were assigned by the President on November 20, 1979 to the National Oceanic and Atmospheric Administration (NOAA) of the U. S. Department of Commerce.[9] On June 20, 1980, the NOAA issued a document setting forth issues and options being con-

38-036 O - 84 - 13

sidered by the Federal Administration in the development of its 1982 fiscal year budget and legislative program.[10]

C. *Congressional and Executive Interest in Future Spoce Endeavors*

In the U. S. Congress 96th session, both houses of Congress have held hearings in good part to ascertain and encourage private sector involvement in space activities[11] and to evaluate the current U. S. Civil Space Policy. The Policy, announced by the President on October 11, 1978, increased participation by the private sector in space enterprises. Among other recitals, the announcement stated that the Policy was to "confirm our support of the continued development of a legal regime in space that would assure its safe and peaceful use for the benefit of mankind."[12]

There is no doubt that the Administration and the Congress desire to assure that the private sector, under Government aegis, will share in such space endeavors as envisaged by the concise apropos remarks of Ambassador Peter Jankowitsch, Chairman of the UN COPUOS,[13] at the opening of the Committee's 1979 session:

> We are now seriously considering daily flights to orbit which might serve and supply large technical facilities such as research laboratories, astronomical laboratories, earth resources observatories, manufacturing facilities or communication centres. We are also considering expanding direct-to-home television broadcasting through-out the world; and erecting large structures in space, stabilizing them and moving them about. The possible early demonstration of a large structure that could be part of a large

A White House Press Release of June 20, 1978 announced the Committee's establishment within the Executive Office of the President with the objective among others, of "[the encouragement of] domestic commercial exploitation of space capabilities and systems for economic benefit . . .". *Id.* at 559.

13. United Nations Committee on the Peaceful Uses of Outer Space [hereinafter cited as COPUOS].

solar experiment is under active consideration. And finally, we are examining the possibility of setting up larger, earth-like communities several hundred thousand miles up in space.[14]

D. Activities in the Moon and other Celestial Bodies

The TOM expressly recognizes that the private sector may engage in activities on the moon. In language patterned after Article VI of the OST, the TOM states that "non-governmental entities" under the jurisdiction of a State Party to the Treaty may engage in national activities on the moon. However, such activities are to be "only under the authority and continuing supervision of the appropriate State Party."[15]

It should be noted that by reason of express recitals in the initial article of the TOM, its provisions relating to the moon are also applicable to other celestial bodies other than the Earth, including "orbits around or other trajectories to or around" the moon.[16] However, such orbits and trajectories "do not include trajectories and orbits of space objects in earth orbit only and trajectories of space objects between the earth and such orbits."[17] In this paper, all references to the moon shall likewise be deemed to be applicable to other celestial bodies, unless it is otherwise apparent from the context.

IV. EXPLOITATION OF MOON RESOURCES

A. The Common Heritage Principle

The provisions of the TOM of most significance to commercial operations under the Treaty concern the exploitation of the natural

---

14. Report of COPUOS, 34 U.N. GAOR, Supp. (No. 20) 30, U.N. Doc. A/34/20 (1979).

15. TOM, *supra* note 1, at art. 14, para. 1. The wording of the prior Art. VI, OST was taken from para. 5 of 18 U.N. GAOR, Supp. (No. 15) 15, U.N. Doc. A/5515 (1964). Declaration of Legal Principles Governing Activities of States in the Exploration and Use of Outer Space. The wording was that proffered by the U.S.S.R. except for substitution on the suggestion of the U.S. Delegate of the term "non-governmental entities" for "non-governmental bodies corporate" 18 U.N. GAOR ____, ____, U.N. Doc. A/AC.105/PV.24 (1963). In a discussion leading to the formulation of this principle, the Soviet Delegate remarked:

> The Soviet delegation considers it essential to point out that in this field it would be possible to consider the question of not excluding from the declaration possibility of activity in outer space by private companies, on the condition that such activity would be subject to the control of the appropriate State and the State would bear international responsibility for it.

16. *Id.* at art. 1, para. 2.

17. *Id.* at Preamble; Report of the COPUOS, *supra* note 13, at 11, para. 63.

resources of the moon. It was after a stalemate of seven years that a compromise permitted the attainment of a consensus on the present draft. This compromise is contained in Article 11, which states in its initial paragraph: "The moon and its natural resources are the common heritage of mankind, *which finds its expression in the provisions of this Agreement, in particular in paragraph 5 of this article*."[18] (emphasis added). The compromise provision was the addition of the emphasized wording purporting to limit the derivation or meaning of "common heritage of mankind" to the TOM, rather than to the use of such phrase elsewhere.

A brief review of the development of the common heritage of mankind concept (hereinafter referred to as the "CHM") in the TOM may be helpful. The 1971 UN General Assembly session requested COPUOS and its Legal Subcommittee to consider, as a priority matter, the question of the elaboration of a draft treaty concerning the moon.[19] In its request, the Resolution took note of "A Draft Treaty Concerning the Moon" submitted by the USSR to the UN General Assembly's First Committee.[20] This draft, however, was devoid of the CHM. Such concept had previously been proposed by Argentina during the 1970 COPUOS Legal Subcommittee Session in a proposal concerned only with the use of the natural resources of the moon and other celestial bodies.[21] The concept was adopted by the United States in the draft proposal it submitted in April 1972[22] at the COPUOS Legal Subcommittee Session which was considering the desirability of a TOM pursuant to the request of the UN General Assembly. The CHM was concisely stated in the U. S. draft as "The natural resources of the Moon and other celestial bodies shall be the common heritage of all mankind."[23]

It would appear that the U.S., at the time of the submittal of the CHM had in mind the similar recital in the proposed Law of the Sea (LOS) seabed treaty. On May 3, 1972, the U.S. Representative to the Legal Subcommittee in a statement concerning the natural resources of the moon and other celestial bodies stated: "This [CHM] would parallel policy proposed by President Nixon

two years ago . . . that all nations should regard the resources of the seabed . . . as the common heritage of mankind."[24]

The U.S. introduction of the CHM met with mixed reception. The USSR opposed the CHM[25] until it accepted as as a compromise the more limiting revised Article 11 which contained the additional circumscription to the CHM: "which finds its expression in the provisions of this agreement, in particular in paragraph 5 of this article."[26] Paragraph 5 provides:

> States Parties to this Agreement hereby undertake to establish an international regime, including appropriate procedures, to govern the exploitation of the natural resources of the moon as such exploitation is about to become feasible. This provision shall be implemented in accordance with Article 18 of this Agreement.[27]

B. The International Regime

The international regime's main purposes as recited in Article 11, paragraph 7, are the orderly, safe development and rational

24. Statement by U.S. Representative Herbert Reis, contained in U.S. Mission release, Geneva, Switzerland, May 3, 1972, p.6. In an exchange of views, with the U.S.S.R. during the following year session of the Legal Subcommittee as to the legal substance of the CHM, the Argentine delegate observed that the UN General Assembly Resolution 2749 25 U.N. GAOR, Supp. (No. 28) 24, U.N. Doc. A/8028 (1971) adopted without dissenting vote, was "proof of the existence of this legal viewpoint common to all States, irrespective of their special internal features, their philosophical ideas or their policies" ___ U.N. GAOR, ___, 29-31, U.N. Doc. A/AC.105/115 (1973). The referenced Resolution in part declared: "1. The seabed and ocean floor, and the subsoil thereof, beyond the limits of national jurisdiction . . . as well as [its] resources . . . are the common heritage of mankind." 25 U.N. GAOR, Supp. (No. 28) 24, U.N. Doc. A/8028 (1971).

25. *See* U.S.S.R. Working Paper, 28 U.N. GAOR ___, ___, U.N. Doc. A/AC.105/101, para. 21 (1973) *reprinted in* 1977 COPUOS Legal Subcommittee Report, 32 U.N. GAOR ___, ___, U.N. Doc. A/AC.105/196, Annex I, 11-12 (1977). The U.S.S.R. favored substitution of the prior used and understood phraseology "common province of all mankind," observing that under the OST celestial bodies "are available for the undivided and common use of all States, but not jointly owned by them. This is the essential feature of international law."

In 1976, Ambassador Piradov of the U.S.S.R., at the COPUOS, observed: "First, we are genuinely convinced that such a proposal is premature in the absence of the necessary objective foundations and factual material for it. Secondly, we have referred to the juridical and political vagueness and lack of specificity in the concept which has been put forward." 31 U.N. GAOR ___, ___, U.N. Doc. A/AC.105/PV 158, 8-10 (1976).

26. TOM, *supra* note 1, at art. 11, para. 1.

27. Art. 18 provides that the question of whether exploration is about to become feasible will be an agenda item of the UN General Assembly ten years after the TOM has come into force; further such question may also be considered by a review committee after the TOM has been in effect for five years, upon the request of one-third of the States Parties to the TOM with the concurrence of a majority of the States Parties. TOM, *supra* note 1, art. 18.

management of the moon's natural resources, the expansion of opportunities for the use of such resources, and an "equitable sharing" in the "benefits derived from the resources" by all States Parties, with "special consideration" being given to the efforts of those countries which have contributed either directly or indirectly to the exploration of the moon as well as to "the interests and needs of the developing countries."[28]

1. PRIVATE SECTOR CONSIDERATION

Intrinsic to the consideration of the international regime are questions relating to authorization for exploitation of the moon's natural resources, the nature and limitations of the international regime, and when such regime and exploitation may come into effect. In the United States, serious consideration is being accorded to assertions that the CHM will lessen the incentive of the private sector to risk capital investment in space ventures involving exploitation of the moon's resources. The purpose of any commercial venture being financial gain, the indefiniteness of the CHM is said to render the possibility of such gain as too speculative and uncertain, including an unacceptable possible interpretation for sharing profits from risk capital investments with parties that did not share such risk.

It must be recognized that unlike the seabed whose resources are readily identifiable and obtainable, many years of effort—perhaps thirty or more—and unknown costs will be expended before exploitation of the moon can be determined as "about to become feasible."[29]

---

28. TOM, *supra* note 1, art. 11, para. 7.

29. Charles Sheffield, President, American Astronautical Society and Vice-President, Earth Satellite Corporation, in recent testimony stated "these parameters may not be known well enough for another thirty or forty years to encourage a private investment group to operation on a for-profit basis in the field of off-earth mineral exploration." *The Moon Treaty, Hearings Before the Subcomm. on Science, Technology and Space of the Senate Comm. On Commerce, Science and Transportation*, 96th Cong., 2d Sess. 92 (1980) [hereinafter cited as *The Moon Treaty Hearings*]. Frosch, Robert, NASA Administrator, at the same Hearing testified that "[a]ny exploitation of extraterrestrial resources will require the development of new major technologies, . . . that planetary exploration will be required in order to fill the gaps in our knowledge of the nature and distribution of extraterrestrial materials." *Id.* at 37. He also observed that "a number of evolutionary steps of technology would be required to accomplish a demonstration of a Space Materials System." *Id.* at 38.

For an excellent presentation of lunar resources available, materials separation and processing to be undertaken, *see* testimony of Edward Bock, Project Engineer at Convair Div., General Dynamics Corp., and of Dr. James R. Arnold, Department of Chemistry, Univ.

2. THE MORATORIUM ISSUE

Other questions have been raised as to the nature and authority of the international regime envisaged by the TOM and whether a moratorium on exploitation of the moon's natural resources is required pending establishment and functioning of such regime. Further questions remain as to the possessory interest of a State or its nationals to the area of the moon occupied during exploitation of natural resources and to the resources removed.

C. Interpretation Problems

A reading of the TOM text, without consideration of its negotiated history, can be misleading. TOM contains key words that are undefined and which may infer an unintended meaning. In the COPUOS and its two subcommittees, agreement on a matter under consideration is obtained by consensus; that is, agreement is not obtained until no further objection is made. As objections are made, piecemeal changes are suggested. While the intent of a change would be clear at the time made, a reader of the entire provision not having the benefit of the detailed consideration accorded the total effort may readily arrive at a conclusion not in accord with the intent of the provision.

With forty-seven States represented at COPUOS and its subcommittee meetings, with each annual meeting able to allocate limited time for consideration of a given agenda item, with language difficulties sometimes occurring, and with the need to coordinate with home offices on changes of substance, the pressure for consensus on a General Assembly priority requested item may lead to reluctance to seek substantial revision when a recited interpretation appears to provide an acceptable resolution. With many cooks in the kitchen, we may question the appearance of slowly baked pie when removed from the oven; while digestibility

of California at La Jolla. *Id.* at 147-64. *See also* Stanley Sadin, Dep. Dir., for Special Program Development at NASA's Office of Aeronautics and Space Technology, address at a Space Law Workshop, sponsored by the Association of United States Members of the International Institute of Space Law, at the Annual Meeting of the American Society of International Law, "The Moon Treaty: Should the United States Become A Party?" (Washington, D.C. 1980). After advising of the moon's resources and the method contemplated for their removal and transportation, Sadin observed that the most promising present utilization envisioned was in construction of a Solar Power System satellite space station. He cautioned, however, that this would first require many years of study and research.

may be difficult, it may nevertheless provide the needed sustenance.

1. The Vienna Convention on the Law of Treaties

In resolving questions raised as to the interpretation of provisions of a treaty or agreements incident thereto, Part III, Section 3 of the "Interpretation of Treaties" of the Vienna Convention on the Law of Treaties permits reference to UN documentation of the negotiated history and conclusion of the treaty, including agreements as to its interpretation.[30] It may be further noted that the "negotiated history" of a treaty includes "all manifestations of intention made during the course of negotiation . . . contained in the official records of the conference available to negotiators."[31]

---

30. U.N. Doc. A/Conf. 39/27 *opened for signature*, May 23, 1969, *reprinted in* 8 Int'l Legal Mat'ls 679 (1969). The U.S. has not yet become a party to the Vienna Convention; however, its provisions here applicable reflect customary international law, and are as follows:

Article 31

General rule of interpretation

(1) A treaty shall be interpreted in good faith in accordance with the ordinary meaning to be given to the terms of the treaty in their context and in the light of its object and purpose.

(2) The context for the purpose of the interpretation of a treaty shall comprise, in addition to the text, including its preamble and annexes:

(a) any agreement relating to the treaty which was made between all the parties in connexion with the conclusion of the treaty;

(b) any instrument which was made by one or more parties in connexion with the conclusion of the treaty and accepted by the other parties as an instrument related to the treaty.

(3) There shall be taken into account, together with the context:

(a) any subsequent agreement between the parties regarding the interpretation of the treaty or the application of its provisions;

(b) any subsequent practice in the application of the treaty which establishes the agreement of the parties regarding its interpretation;

(c) any relevant rules of international law applicable in the relations between the parties.

(4) A special meaning shall be given to a term if it is established that the parties so intended.

Article 32

Supplementary means of interpretation

Recourse may be had to supplementary means of interpretation, including the preparatory work of the treaty and the circumstances of its conclusion, in order to confirm the meaning resulting from the application of article 31, or to determine the meaning when the interpretation according to article 31:

(a) leaves the meaning ambiguous or obscure; or

(b) leads to a result which is manifestly absurd or unreasonable.

31. Restatement (Second) of Foreign Relations Law of the United States § 147 (1965).

2. Contending Interpretations

While the CHM, on introduction into the TOM, may have contemplated the concept as used in the LOS seabed treaty, it is clear that the revision accepted on the last day of the 1979 COPUOS session removed the LOS use as a binding interpretation and restricted the CHM meaning to the provisions of the TOM, particularly Article 11, paragraph 5. The question, however, remains as to what the latter may embrace. It will be recalled that in the referenced paragraph 5, the Parties "undertake to establish an international regime . . . to govern the exploitation of the natural resources of the Moon as such exploitation is about to become feasible."[32] Further, by paragraph 7(d), Article 11, the Parties to the TOM agreed to an "equitable sharing" in the benefits derived from such resources, as previously related herein.[33]

Views have been expressed by respected authors as to their belief of the meaning of the CHM as used in the TOM, ranging from application of the LOS purported use of CHM[34] (common ownership and profit sharing) to meaning the international cooperation that exists today in the equitable sharing of benefits of space applications with the international community.[35] Richard G. Darman, a lecturer in Public Policy and Management at the John F. Kennedy School of Government, Harvard University, in discussing Article 11 of the TOM, observed that the CHM "in and of itself, is but a vague phrase"; he noted that the international regime is similarly without specific definition, such essentially being left to future negotiations; and that neither the TOM nor the LOS seabed treaty negotiating text "refers to the other or to the other's specific domain."[36]

Ambassador Aldo A. Cocca, who, as the Representative of

32. TOM, *supra* note 1, art. 11, para. 5.

33. *Id.* at art. 11, para. 7(d).

34. *The Moon Treaty Hearings*, *supra* note 29, at 105-132 (testimony of L. Ratinen).

35. U.N. General Assembly Press Release USUN—107 (79), Nov. 1, 1979 (statement by R.W. Petree to the U.N. General Assembly Special Political Committee in Consideration of the TOM draft) [hereinafter cited as Press Release].

Robert B. Owens, in testimony on the TOM, stated "our position in essence was that the common heritage concept . . . would simply parallel and conform to established space law, especially Articles I and II of the Outer Space Treaty . . . and that activities in such areas [of outer space] shall be for the benefit and interests of all countries." *The Moon Treaty Hearings*, *supra* note 29, at 13.

36. *The Moon Treaty Hearings*, *supra* note 29, at 168.

Argentina, first proposed the CHM at a COPUOS Legal Subcommittee Session in 1970, has recently written:

> As you know, it is rather dangerous to crystallize in a definition the principle involved in a concept which is just being born in the new domain of Space Law, such as the 'common heritage of all mankind,' as it was established in the Moon Agreement. As the 'international regime' is concerned, I dare say it is not a matter of definition; I feel it must be the outcome of the implementation of the guidelines set forth in the agreement.[37] Similar caution has been suggested by USSR[38] and US[39] COPUOS delegates.

V. THE NEED FOR LAW AND ORDER IN SPACE

A. Avoidance of Anarchy

The OST has assured that unlike discovery and exploration on Earth, a nation's sovereignty shall not attach to space, the moon or other celestial bodies by reason of space exploration or other action. With the advent of the Space Shuttle, we are at the threshold of a great expansion in space activities. "Anarchy in space could be more dangerous than anarchy on Earth," observed the late Justice Kenneth B. Keating.[40] It is plausible that international controls be sought for the common good of all States. While a "regime" conceivably can be but an agreed set of govern-

---

37. Letter from Dr. Cocca to Mrs. Eilene Galloway, *reprinted in* SENATE COMM. ON COMMERCE, SCIENCE AND TRANSPORTATION, 96th CONG., 2D SESS., AGREEMENT GOVERNING THE ACTIVITIES OF STATES ON THE MOON AND OTHER CELESTIAL BODIES 58 (Comm. Print 1980).

38. Dr. Y.M. Kolossov, Alternate Head of the Soviet Delegation at the 1979 COPUOS session, on the last day of the session when the U.S.S.R. accepted the more limited CHM, observed: "Our delegation will make no hasty interpretation of the meaning behind each article of the new draft agreement . . . ." 34 U.N. GAOR ____, U.N. DOC. A/AC.105/PV.203, at 21 (1979).

39. S. Neil Hosenball, who chaired the U.S. delegation at the 1979 COPUOS session, in response to questions at a Congressional Hearing on September 6, 1979, observed:

> The world . . . may be a lot different when exploitation is proven feasible on a commercial scale, and that common heritage may mean something completely different then . . . . The definition of the Law of the Sea is being hammered out in the implementation of the exploitation of the natural resources . . . . Unlike the Law of the Sea, where we do have some information on the investment required where we do have technology and facilities . . . that can harvest the resources [of the seabed]. We're a long way from that in space activities. . . . So . . . it should not have a definition at this time. I don't think we know enough in a space context to try to define it. *International Space Activities, 1979: Hearings Before the Subcomm. on Space Science and Applications of the House Comm. on Science and Technology*, 96th Cong., 1st Sess. 96-97 (1979) [hereinafter cited as *Int'l Space Activities*].

40. 105 CONG. REC. A1822 (1959).

ing principles, the facts and circumstances may require a more institutionalized arrangement. Establishment of an international agency or authority, with defined powers and procedures[41] to govern exploitation of the natural resources of the moon, should provide a needed control on behalf of all States. It would also serve to protect the biosphere[42] and the existing balance of the environment as well as assure equitable sharing in the benefits derived from the exploited resources.

The esteemed Honorary Director of the International Institute of Space Law and founder of the Association of United States Members of the International Institute of Space Law, Mrs. Eilene Galloway, in recent testimony during a U.S. Senate subcommittee Hearing on the TOM observed:

> The problem posed by the Moon Treaty is how to translate general guidelines that express value judgments into practical arrangements for the operation of scientific and technical facilities. And beyond that, how should fair arrangements be worked out between national and international relationships?[43]

B. The Role of the International Regime

It will be in the international regime, and appropriate procedures, agreed upon in the contemplated subsequent international agreement[44] that will ultimately determine the breadth of the TOM's CHM and equitable sharing principle. While this agreement may be extremely difficult to conclude,[45] deferment of mak-

(This reference is to a discussion of utilizing the International Civil Aviation Organization (ICAO) as an model for future international control of space flight).

42. *See* TOM, *supra* note 1, art. 7, para. 1.

43. The *Moon Treaty Hearings*, *supra* note 29, at 179.

44. While the language in the TOM is not explicit as to a subsequent separate treaty, the negotiated history has several such recitals. For example, in his statement to the COPUOS Legal Subcommittee concerning the natural resources of the moon under the proposal advanced by the U.S. relative to exploitation of the natural resources of the moon, Herbert Reis, the U.S. Representative to the Subcommittee, observed: "Finally, we would need to contemplate a special treaty-drafting conference in the event of the discovery of commercially exploitable resources. . . ." A similar recital for a separate treaty was also made by Ambassador Richard W. Petree in his remarks on Nov. 1, 1979 to the U.N. General Assembly Special Political Committee, *supra* note 28, at 6.

45. Aside from the nature and procedures to be determined, there will be many other matters to be considered. For example, should benefit sharing be extended to activities to which the exploited resources are applied? If so, should a space station utilizing moon materials in its construction and operation be included? Does it extend to raw products and finished manufactured items from such space station? It should be noted that in response to

ing the determinations involved permits, at this time, the acceptance of the TOM principles and direction for international cooperation in undertaking activities on or about the moon, including research and development efforts for new products and processes, space stations and habitats and ascertainment of the feasibility of commercial exploitation of the natural resources of the moon. It is to be hoped that data will be forthcoming to provide a firm basis for specificity as to the type of international regime to be established and for defining the equitable sharing in exploitable resources.

It has been the reported position of some States and attorneys that exploitation of the natural resources of the moon would not be lawful under the present state of Space Law.[46] The doubt that has existed as to lawfulness of exploitation of the moon's resources will be removed by the TOM's providing for such exploitation. It is to be hoped that this provision will encourage private sector investment in such endeavors. The need to encourage such investment has been noted as a must item for subsequent conferences seeking to establish the international regime.[47]

VI. PROPERTY RIGHTS ON THE MOON

A. General Prohibition

It may be noted that under the text of then Article X of the draft TOM, as adopted in 1973 by the COPUOS Legal Subcommittee Working Group, the wording of paragraph 2 read in pertinent part: "Neither the surface of the moon, nor, subject to the provisions of Article V, paragraph 2, their parts and natural resources shall become the property of any State, international intergovernmental or non-governmental organization, national organization or non-governmental entity, or any natural person."[48]

The referenced Article V, Paragraph 2, was to expressly authorize "the right to collect on and remove from the moon

---

a question by Senator Stevenson, during previously referred to Hearings on July 29, 1980, as to whether exploitation benefits would extend to a space station not on the moon, the Legal Adviser of the Department of State, Robert B. Owens, advised that it would not as the Moon Treaty took express note of the COPUOS interpretation that space objects in earth orbit only are not within the TOM (*See* Report of the COPUOS, *supra* note 14, at 11, para. 63).

46. *The Moon Treaty Hearings*, *supra* note 29 at 9 (statement of Robert B. Owens).

47. Reis, *supra* note 24, at 6.

48. COPUOS Legal Subcomm., *supra* note 25, at 19.

samples of its mineral and other substances," and, "in the course of scientific investigations also use minerals and other substances of the moon in quantities appropriate for the support of their missions."[49] It is apparent from the above quotations that the sole exploitation to be permitted was the removal of samples, and additional amounts of minerals and other substances appropriate for the support of scientific missions.

B. The Exploitation Exception

1. THE U.S. "IN PLACE" AMENDMENT

To ensure that the above phraseology would not preclude exploitation, removal and ownership of exploited resources for other than scientific investigation, the U.S. Delegate at the 1973 Legal Subcommittee session, on April 17th, advanced an amending proposal to have the opening sentence of the above quoted then paragraph 2 of Article X, read: "Neither the surface nor the subsurface of the moon or other celestial bodies, nor *any area thereof or* natural resources *in place* shall become the property of . . . " etc. The deletion of the phrase "subject to the provisions of Article V" eliminated the limited authorization for removal of only samples and mineral and other substances in support of scientific investigations. The addition of the words "in place" was explained by the U.S. Representative at the Subcommittee session: "to indicate that the prohibition against assertion of property rights would not apply to natural resources *once reduced to possession through exploitation* either in the preregime period or, subject to the rules and procedures that a regime would constitute, following the establishment of the regime . . ."[50] (emphasis added).

The U.S. amendment was accepted and such recital constitutes Article II, paragraph 3 of the TOM. While a reader without knowledge of the negotiated history may question that the paragraph reflects authority to exploit and to own resources removed, such intent being clearly reflected in the negotiated history must govern.[51]

---

49. *Id.* at 50.

50. *Id.* at 16. This was the April 17, 1973 U.S. proposed amendment to the then Article X, TOM. To explain the words "in place," see Hosenball, *The United Nations Committee on the Peaceful Uses of Outer Space: Past Accomplishments and Future Challenges*, 7 J. SPACE L. 95, 103 (1979).

51. Vienna Convention on the Law of Treaties, *supra* note 30, at art. 31, para. 4; art. 32.

2. APPLICABILITY TO THE PRIVATE SECTOR

As the words "non-governmental entity or any natural person" were in the enumeration immediately following the insertion of the words "in place", the exploitation authorization and resulting ownership authority conveyed would appear to equally extend to the private sector, subject to requirements elsewhere in the TOM such as "only under the authority and continuing supervision of the appropriate State Party" recital of Article 14. This, however, is not an onerous limitation since all enterprises are required to meet applicable legislative regulatory government agency directives, for example, licensing and supervision of commercial air carriers, and coal mining.

C. Assurances to Industry

Industry need not fear an uncertainty premised on the assertions of some critics of the TOM that there is a moratorium on exploitation of the moon's resources. This apprehension is nurtured by a strained construction of Article 11, paragraph 5 which recites that States Parties "hereby undertake to establish an international regime . . . to govern the exploitation of the natural resources of the moon as such exploitation is about to become feasible." The negotiated history of the TOM, by recitals in the official record of the COPOUS and of the UN General Assembly, confirm that no moratorium is intended. Specific proposals for a moratorium in the course of the negotiations failed to obtain the required consensus. The consensus finally achieved on the last day of the COPUOS 1979 session resulted from a compromise in which the more limited CHM recital was accepted upon an express withdrawal of a proposal calling for deferment of exploitation pending the establishment of an international regime to govern such exploitation.[52] The UN General Assembly, in its Resolution[53] commending the TOM and requesting that it be opened for signature at the UN, took specific note of the recital in the 1979 COPUOS Report that "the Committee agreed that Article 7 is not intended to result in prohibiting the exploitation of natural resources which may be found on celestial bodies other than the earth . . . ."[54]

53. TOM, *supra* note 1, at 1.

54. Report of the COPUOS, *supra* note 13, at 11, para. 65.

VII. COMMERCIAL SPACE ACTIVITY

A. General

As previously indicated, several provisions of the TOM and the prior OST pertain to space activity by the private sector. While the TOM applies to activities relating to the moon and other celestial bodies, and to orbits around and other trajectories to or around them, the OST also includes all other space activities.[55] In the latter, the private sector generally would not be concerned with the TOM CHM and international regime limitation problems. However, both the TOM and prior space law treaties impose obligations and provide benefits to the private sector. The following discussion concerns the relationship between the private sector and government in their space activities, including obligations and benefits. Recitals herein shall include referral to the OST and other space law treaties believed appropriate.

B. Government Responsibility for Commercial Sector in Space

Both the TOM and the OST provide that Parties to the respective agreements shall bear international responsibility for "national activities" on the moon whether such activities are carried out by governmental agencies "or by non-governmental entities," and for assuring that national activities are carried out in conformity with the provisions of the international agreements.[56] These articles are designed to ensure responsibility for space activities, inherently international in nature, at the governmental level. The OST and the Convention on International Liability for Damage Caused by Space Objects[57] are concerned with damage caused by space objects, but have limited application to damage occuring on the Moon. This is recognized by the TOM, which envisages future consideration of further liability principles being formulated during the later review conferences contemplated of the TOM.[58]

Compensation for injuries or damages may be presently available under a State's domestic legislation. In the United States, authority is provided the Administrator of NASA and the

Secretaries of the military departments to administratively settle claims arising out of space activities.[59]

C. Jurisdiction and Control of Personnel and Objects in Space

Each State Party to the TOM retains "jurisdiction and control" over its nationals, their space vehicles, equipment, facilities, stations and installations on the moon.[60] Similar jurisdiction under the OST over an object launched into outer space and the personnel (including foreigners) abroad, on a celestial body or otherwise in outer space, is retained by the State on whose registry the launched object is carried.[61] This imposes on a State the requirement to ensure that it possesses the necessary legal authority to exercise such jurisdiction and control. Of course, the State of Registry could waive its jurisdiction in a particular case where another State, under the international law, may also have jurisdiction. Under the "nationality principle," a State may extend its jurisdiction over offenses by its nationals wherever they occur.

A sovereign is obligated under international law to protect its own and foreign personnel lawfully under its jurisdiction. The U.S. Congress is considering enactment of legislation to extend U.S. criminal jurisdiction over offenses committed aboard U.S. launched spacecraft and at places otherwise "outside the jurisdiction of any nation" where the offenses are committed "by or against a national of the United States."[62] This jurisdiction, of course, would embrace offenses on the moon or otherwise in outer space. While more specific recitals in the U.S. Criminal Code are

60. TOM, *supra* note 1, at art. 12, para. 1.

61. OST, *supra* note 2, at art. VIII.

62. S. 1722, 96th Cong., 1st Sess. (1980). The proposed "Criminal Code Reform Act of 1980" was favorably reported out of the Senate Judiciary Committee, with amendments, on January 17, 1980. Its House counterpart, H.R. 6915, 96th Cong., 2nd Sess. (1980) was favorably reported out of the House Judiciary Committee on July 2, 1980. While the short time remaining of the 96th Congress precluded resolution of differences between the Senate and House versions before adjournment the measure is certain to be reintroduced with likely enactment by the 97th Congress. A new, more limited measure is already under consideration as the "National Aeronautics and Space Authorization Act, 1982." H.R. 1257, 97th Cong., 1st Sess. (1981). This measure includes a proposed amendment to 18 U.S.C. § 7 (1976), by adding a subparagraph 6 thereto, to extend the Special Maritime and Territorial Jurisdiction of the United States to space flight. For a discussion of this possible approach, *see* Menter, *Jurisdiction Over Man-Made Orbital Satellites*, 2 J. SPACE L. 19, 22 (1974).

being sought, the NASA Administrator, under authority delegated to him in the National Aeronautics and Space Act of 1958,[63] as amended, on March 7, 1980, issued regulations vesting "absolute authority" in the Commander of the Space Shuttle to enforce order and discipline during all phases of a Shuttle flight, including authority to take action believed necessary for the protection, safety, and well-being of all personnel and on-board equipment and payloads.[64] A violation of the Shuttle Commander's orders would subject the offender to a fine of up to $5,000 or imprisonment for one year, or both.[65] Further note is made that under existing U.S. law pertaining to active duty military personnel, such personnel are subject to U.S. jurisdiction under the Uniform Code of Military Justice for offenses committed thereunder wherever performing assigned duties.[66] The above recitals, of course, also embrace personnel of the private sector participating in space activities.

D. Ownership of Property in Space

Under Article 12 of the TOM, the private entrepreneur retains ownership of his space vehicle, equipment, facilities, stations and installations on the moon. Such property and personnel of the employer are to be accorded the benefits provided astronauts by Article V of the OST[67] and provided for space objects by the Agreement on the Rescue of Astronauts, the Return of Astronauts and the Return of Objects Launched Into Outer Space.[68] Thus, if under the stated circumstances, personnel or property of a private company is found by another State Party to the TOM in other than its intended location on the moon, it should be rescued and returned to the responsible State or its representative. The latter State is to bear the expenses incurred in recovery and return of the property.[69] In the event of an emergency involving threat to the lives of such personnel, they may use the facilities and equipment of any State Party on the Moon.[70]

38-036 O - 84 - 14

VIII. THE ERA AHEAD: OBLIGATIONS AND OPPORTUNITIES

A. Equity Responsibilities

The moon and its natural resources are recited in Article 11 of the TOM as the CHM. Yet under the TOM, neither mankind, nor all States are entitled to share in the benefits of exploitation. The 'equitable sharing' is provided only for State Parties to the TOM. Such States are expressly precluded by paragraph 3 of Article 11 from having property rights in either the surface or subsurface of the moon. Ownership is provided over natural resources of the moon only when no longer "in place." Such ownership accrues to the successful exploiting State. The equitable sharing provided for is not of the resources exploited, nor a division "of" the benefits derived from the resources. Only a sharing "in" the benefits derived "from" the resources are required. This appears a more limited concept than mankind's common ownership of the moon and its resources.

Black's Law Dictionary defines "equitable," in part, as "just, fair and right, in consideration of the facts and circumstances of the individual case."[71] The Dictionary narrates that Justinian is said to have defined 'equity' as "to live honestly, to harm nobody and to render every man his due."[72] While the subsequent agreement for an international regime may establish criteria, it is conceivable that the share "due" to a non-contributing State may be determined to be zero. However, whether the OST concepts or a formula for a greater sharing in the benefits will govern must await the subsequent treaty. If a State Party to the TOM does not accept the subsequent treaty, it nevertheless remains obligated in carrying out its activities with the respect to the natural resources of the moon to do so in a manner compatible with the purposes sought by the international regime specified in Article 11, paragraph 7, of the TOM, including the "equitable sharing" principle.

In a recent presentation, Dr. Stephen Doyle, Program Manager for Telecommunications, Information and Space Studies of the Office of Technology, U.S. Congress, characterized the most recent of the evolutionary phases of Space Law as the "extrater-

---

71. BLACK'S LAW DICTIONARY 482 (5th ed. 1979).
72. *Id.* at 484.

restrial law phase." He marks its beginning with the UN General Assembly promulgation of the TOM in December 1979. The implementation of the new regime of "common heritage" is recited as a "major problem that will demand the best and most creative of our skills." He observed that the 19th century model of exploration and conflict cannot be tolerated in the 21st century. He states however, that "it must be understood that if there is to be no dominion by a few countries, there must be no dominion by the majority. . . ." "Equity" is stated as the "key concept" for realizing the use and benefit of space which is to be available to all nations regardless of their levels of economic development. "But that," Dr. Doyle states, "should not be read to mean that every nation has a right to share equally in benefits regardless of contribution." He further observed that "opportunities must be nondiscriminatory and there must be a possibility for all to contribute to and share in endeavors in space. Returns, however, must reflect contributions. There is no 'free lunch'."[73]

B. Private Sector Investment Encouraged

In the recent Congressional hearing on U.S. Civil Space Policy, the President of the Northrop Corporation, Dr. Thomas O. Paine, a prior Administrator of NASA, narrated successful past and present ventures of private enterprise in space activities. He urged establishment of goals for the future, observing:

> Private enterprise has now raised and invested more than $1 billion in orbiting comsats, with a growth trend that indicates doubling in the next few years. In similar fashion, satellite remote sensing has grown . . . , initiating another new space industry[74] . . . , the routine conduct of opportunistic research in laboratories in space is an activity whose time has come . . . . We need to explore new ideas that utilize the availability of unlimited energy, ready sources of lunar and asteroidal materials[75] . . . . Now is the time to plan and initiate work on the essential initial orbiting bases.[76]

75. *Id.* at 13.

76. *Id.* at 14.

Dr. Paine further testified that we should continue to promote international participation in major space ventures as a positive step in maintenance of peace among the major powers, the further application of space systems to raise living standards around the world, and the sharing of costs and benefits of space activities among all countries.[77] Mr. S. Neil Hosenball, the General Counsel of NASA, chaired the U.S. Delegation to the 1979 COPUOS session. In testifying in House of Representatives Hearings on "International Space Activities, 1979," he observed that a review of the total records of the TOM negotiations over seven years clearly establishes that there has not been any limitation imposed on the commercial exploitation of the lunar surfaces or celestial body resources and that "nothing in the treaty in any way restricts such activity being carried out by industry, by private commercial entities."[78] Recitals of the Treaty have been categorized as "incentives" by Ambassador Richard W. Petree, U.S. Deputy Representative to the UN Security Council. He observed that by setting forth in Article 11, paragraph 7, the purposes governing exploitation of natural resources, "uncertainty is decreased and both State and private entities may now find it possible to engage in the arduous and expensive efforts necessary if exploitation of the natural resources is ever to become a reality."[79]

C. Clarification of "Equitably Sharing"

The difficulty and importance to the international community of attaining the later agreement for an international regime is apparent. Realism would suggest a pragmatic approach by all interests. Without adequate inducement to States and, where applicable, to their "non-governmental entities" concerned, the effort to determine feasibility of moon resources exploration will falter. In countries where the private sector plays a predominant role in industrial production on a profit basis, such sectors must be assured that the risk is reasonable and within permissive limits.

It is believed that the early fears expressed by the private sector have been exaggerated. Nor should a requirement to share profits, should such extreme determination be within the authority of the international regime, itself be the sole basis of the private sector's refusal to advance risk capital in a national

77. *Id.* at 16.

79. Press Release, *supra* note 35.

endeavor for exploitation of the natural resources of the moon. U.S. industry has not declined participation in foreign government ventures with sharing of profits in high risk situations, such as in petroleum endeavors, viz: oil drilling, exploration, processing or refinement, production and distribution. Neither has it declined to risk capital in payment to the United States for leases to explore for oil in US owned lands, including seabeds and mountain shale, or for mineral rights exploration.

As previously indicated, it will be many years before exploitation of the moon's resources becomes feasible. It is reasonable to assume that costs involved would be recouped before any equitable sharing may begin. At the later exploitation stage, could not the sharing of profits be construed as a condition for participation in the project similar to the referenced foreign petroleum ventures, or as an overhead cost akin, in part, to overhead rental for the exclusive moon area utilized. As such exploitation is a national activity under the TOM, should not some tax considerations be accorded by the sponsoring government?

D. Government-Industry Cooperation

The great success of the United States space effort has been based upon the close cooperation between Government and industry. The Government policy is to retain a major space research and development endeavor until it becomes commercially feasible. Turnover to the private sector at that time would not necessarily terminate further research and development by the Government in such area. While the Government funds its research program, it calls upon industry to share in concept development and to produce and test necessary hardware.

In the development of a national capability to exploit the moon's resources, Governments will employ their industrial capability to achieve their goals. Costs therefore will primarily be borne by Government whether functioning through governmental or non-governmental entities. Additional incentives to industry may be manifold, *e.g.*, study grants, cost plus payments, and loan guarantees. In a recent legislative proposal, for example, Congressman Donald Fuqua, Chairman of the Committee on Science and Technology of the House of Representatives, has proposed legislation to encourage private sector interest in space activities participation. This measure, H.R. 7412, 96th Congress, 2nd Session, introduced on May 21, 1980, sought to establish a "Space In-

dustrialization Corporation" to provide Government secured investment capital for high technology space ventures which otherwise may exceed acceptable risk to private sector elements.[80]

Chairman Fuqua has recently written that prospects for further improvement of goods and services "will move nations to expanded uses of the space environment that will reap countless economic and societal benefits."[81] He further observed: "We are on the threshold of industrializing space and the role of private enterprise will determine the success of these endeavors . . . ."[82]

E. Government Leadership and Support

Nations in the past, whatever their ideology, have not hesitated to bear the majority of, if not all, expenses incident to desired high risk endeavors. Where private enterprise exists, governments have tailored legislation on the subject concerned as an inducement for private sector participation (*e.g.*, in shipping, railroading, air carrier transportation, and atomic energy).

In the United States, both the Executive and Legislative branches of the Government are currently evaluating concepts to induce private sector participation in space activities. It is incumbent upon the private sector to advise the Government of its interests, capabilities and limitations as specific activities are addressed (including, should the U.S. become a Party to the TOM, recommendations for the future treaty to provide an international regime to govern exploitation of the natural resources of the moon). The Government in turn must assure industry protection from unacceptable risk until economic feasibility is apparent.

F. U.S. Consideration of Acceptance of the TOM

While U.S. leadership was the moving force in the UN's

---

80. H.R. 7412, *supra* note 11, was introduced on May 21, 1980 by Congressman Fuqua for himself and fifteen others. It was to have been cited on enactment as the "Space Industrialization Act of 1980." The bill provided for the establishment of a Space Industrial Corporation to promote new products, processes, services, and industries using the properties of space technology. The measure sought to provide a high degree of assurance that the private entity could depend upon security in handling competitive information, private ownership of patent and proprietary data, and the ultimate sharing in the benefits of the competitive venture. H.R. 7412 was a successor bill to H.R. 2337, 96th Cong., 1st Sess., also introduced by Congressman Fuqua.

81. Fuqua, *Space Industrialization: Some Legal and Policy Considerations for Private Enterprise*, 8 J. SPACE L. 1, 2 (1980).

82. *Id.*

favorable consideration and endorsement of the TOM, it is probable that the contending interpretations discussed above will preclude the U.S. from becoming a Party at the time of the TOM's entrance into force. The caution of private industry towards commitment of substantial capital in risk ventures before clear resolution of contending issues in exploitation of the moon's natural resources is recognized. Involved are questions of the validity of exploitation, title to (ownership of) exploited resources, possible sharing (CHM) of resulting benefits, role and time of coming into effect of the proposed regulatory regime, and the obligation of private sector participants if the international regime is not established.

Granted that the wording of the TOM raises serious questions as to interpretation, it is believed that the negotiated history of the TOM does substantiate the meaning intended by its drafters which accords with the prior Space Law treaties and is in the interest of U.S. private enterprise and the world community.

To assure that the issues raised are consistently resolved in accord with the meaning of terms and intent reflected in the negotiated history, the author suggests that the U.S. in actions supporting the TOM—such as in signing the TOM and/or during the Senate ratification process—should set forth its written "understanding" of each of the contending issues with reference to the negotiated history substantiating its conclusions. These "understandings," under customary international law as well as under the Vienna Convention on the Law of Treaties, are considered as reservations.[83] Thus, an objection by another State adherent must specifically reject the U.S. recital of understanding to preclude entrance of the Treaty into force between them. If no such objection is made within one year, the U.S. understanding is deemed accepted.

G. For All Mankind

In the interests of avoiding seeds for conflict encountered through history on Earth, the world community tailored the OST to a new set of legal principles proclaiming outer space and its celestial bodies as the province of all mankind and that its exploration and use shall be carried out for the benefit of all peoples.

---

83. Vienna Convention on the Law of Treaties, *supra* note 30, at art. 19; art. 20, paras. 4(b), 5; art. 23.

Space activities, since the OST came into force in 1967, have brought great benefits to the world community. The private sector has participated and profited. It is believed that rather than limit private sector opportunities, the TOM will enhance them by opening new vistas with rewards, as in the past, dependent upon initiative, ingenuity and industrial capability, with government support tailored to high risk endeavors.

Continued international accord is essential for preventing friction in space. This is of equal concern to all States. Greater participation of non-space powers in space activity should better ensure bringing to fruition its many benefits for all mankind. Such cooperation should further assure peaceful coexistence in space and on our Spaceship Earth.

Martin Menter, of Counsel, Meyers & Alterman, 1710 Rhode Island Avenue, N.W., Washington, D.C. 20036. General Menter has asked that footnote 1 on page 214 include the following note: The Moon Treaty became effective on July 11, 1984 upon deposit of the instrument of ratification of the Fifth ratifying State; however, neither the U.S. nor the U.S.S.R. has yet ratified or become a signatory to the Treaty. General Menter has indicated other changes which have not been published and therefore have not been included in the above version of the article.

COSMIC COUNSELOR

By Ron Bitto

OMNI PROFILE

International law could block space efforts by private enterprise — but not if lawyer Art Dula has his way

After meeting Art Dula, it's easy to picture him 25 years from now. Seated in a geodesic lunar courtroom, his ample figure lends an authoritative bulge to his judicial jump suit. He leans forward on the bench and begins his history lesson. Space law, he points out, traces its roots to the Corpus Juris of the Roman Empire. The two lawyers he's lecturing have heard it before, but they listen respectfully to the moon's first federal jurist. Then Judge Dula reads his decision, settling a corporate dispute over molybdenum mining in the Sea of Tranquillity. He allows extraction to begin immediately.

Today, at thirty-three, Arthur M. Dula is a blend of technologist and legal historian, an ardent advocate of free enterprise who looks to the past for guidance and to the future for vast new opportunities. He is probably the first private attorney in America to devote his practice solely to aerospace and technical law.

Dula's office occupies the second floor of a restored Victorian house in Houston's Heights, an inner-city neighborhood slowly being redeveloped. A topographical map of Mars hangs behind his massive desk, above his right shoulder. He talks enthusiastically into the telephone. To burn off nervous energy, he pulls an ivory-handled .45 automatic from the desk drawer, removes the clip, and lines up the cartridges on

his blotter like a row of tin soldiers. Then he reverses the process, slowly reloading the gun and returning it to the drawer.

Last week a delegation of European lawyers attended a seminar on technical law that Dula conducted at Louisiana State University Law School. During the course he promised them a tour of the Johnson Space Center, in Houston. Today he is phoning one of his many contacts at NASA to arrange the visit.

"We've got to impress them with the space program," Dula asserts repeatedly. "We've got to show that America is serious about putting business into space. These guys are from Europe's biggest banks and financial institutions. Can't we arrange for something off the public tour to make them feel special?"

Dula's friend bends a few rules to set up a Saturday tour.

While Dula often sounds like a self-appointed public-relations man for the American space program, his true vocation lies not in promoting NASA but in helping companies solve the legal problems of introducing new technology and making a profit from it on Earth and in space.

Dula's practice is wide-ranging. A few of his clients are earthbound. One is a Mexican company trying to introduce a new windmill to the United States. Another has developed a way to produce electricity and fresh water from ocean waves. And a client on the East Coast has a chemical process that turns wood chips directly into ethanol, eliminating the energy-intensive distillation now used to produce gasohol.

But several of his clients hope to profit from space itself. Dula acts as a patent lawyer for Eric Drexler, who has invented an improved solar sail. And he represents a company that has developed a new type of rocket engine. He also works for a group of businessmen interested in launching a private space vehicle.

Often his clients' space technologies offer benefits for life on Earth. One company Dula represents has developed a way to refine moon rocks and extract such elements as oxygen, silicon, aluminum, and titanium. "Lunar material seems an awful lot like the fly ash collected in precipitators at coal-fired power plants," the Texas attorney points out. "Every year, electric utilities in this country collect enough of this ash to fill the Grand Canyon. This technology could turn one of our most noxious wastes into a valuable resource."

"The more I get involved in high technology," he notes, "the more I see this synergy between aerospace and Earth. Technology developed for space almost always has benefits on Earth."

Dula's clients take up only part of his time. Much of the rest he spends as a legal theoretician, writing about laws that could enable business to operate profitably in space. Dula sees a bright future for mankind beyond Earth's gravity.

"The great fortunes of the next century will be made in the asteroid belt," the attorney maintains. By the year 2020, "a significant fraction of humanity's gross world product will be derived from space-based activities."

Transportation to Earth orbit will be routine and inexpensive by then, he expects, and solar-sail spacecraft will routinely traverse the inner solar system. Mature businesses will manufacture goods, generate electricity, and gather information in orbit, while private enterprise will be exploiting asteroidal minerals that are processed in orbit.

"Once profit—that is, new, real wealth—begins to flow back to Earth," Dula projects, "investment in space operations will accelerate as world corporations go after profits greater than those possible on the postindustrial Earth."

"Unfortunately, the laws that govern technology—and particularly space law—are evolving at a much slower pace." That leaves many gray areas where the law has not been set. And to Dula, these ambiguities are more than dry legal theory. They could, he believes, discourage investment in space. At least one might even block space development by private enterprise entirely.

"Unless we develop some practical laws to govern our activities in space, we shouldn't be surprised when war breaks out over who has the right to develop the solar system."

Part of the problem lies with NASA itself, Dula feels. In 1978 he wrote a report for the agency detailing the ten most important factors inhibiting participation in the shuttle program by nonaerospace companies. Most were rooted in the NASA Act, our national space law.

For example, NASA controls America's only launch facilities and has discouraged the development of private booster systems. The agency retains all patent rights to technologies developed in operations that involve it in any way, and its administrator can reveal any trade secrets used in experiments on the shuttle. This alone is enough to keep many companies that rely on unique technology from launching experiments on the shuttle.

And Dula believes that NASA's charter discourages cooperation with companies other than the aerospace giants. The agency is set up both to promote space activities and to regulate them. In short, concerns that deal with NASA tend to become captive industries.

Moreover, NASA's policy has been to concentrate on the academic and military use of space, playing down commercial possibilities. Communications and weather satellites—the two areas where space technology is improving life on Earth and doing so at a profit—are outside NASA's jurisdiction. They are handled by Comsat and the National Oceanographic and Atmospheric Administration, respectively.

By neglecting commerce while working closely with big aerospace contractors, NASA has failed to tell potential shuttle customers about the opportunities in space. Dula proposes to remedy this with a more aggressive public-relations program for NASA. He also suggests teaming nonaerospace companies with experienced space contractors to help the newcomers deal effectively with the agency.

Dula's concern with such issues is an old one. Robert Heinlein's science fiction convinced him long ago that mankind should not be limited to its home planet. Heinlein's works even influenced his choice of schooling. "I agree with Mr. Heinlein," Dula says, "that anyone who doesn't understand math ought to learn it. It's basic to understanding the universe." And in a technical society, he knew, even a lawyer needs a strong background in science. So as a prelaw student at Eastern New Mexico University, Dula majored in chemistry and took his minor in mathematics.

He has since built a collection of Heinlein first editions, and the science-fiction art that lines his office includes a watercolor by Ann Layman Chancellor depicting the opening scene of Heinlein's novel *Citizen of the Galaxy*. "Heinlein himself saw the picture at an art show and recognized it as the scene from his book," Dula remembers with a smile.

Leaving New Mexico, Dula went to Tulane University's law school, in New Orleans, where he made the law review. He retained an ambition to manufacture starships, but he also gained a deep interest in Earth's legal traditions. Today his science-fiction library shares a room with a collection of ancient lawbooks.

This interest in the history of law clearly marks Dula's approach to space law. "The Romans gave nations jurisdiction over their territory from hell up to the sphere of the fixed stars," Dula points out. "That's where we get our concept of airspace. So the Roman Code is really the starting point for laws governing space."

But a more recent episode of history has even clearer implications for space development, Dula feels. "Whenever academic laws have been arbitrarily projected into the future," he says, "there have been disastrous consequences. When Pope Alexander the Sixth drew the Line of Demarcation in the year 1494, dividing the New World between Spain and Portugal, he left out England and France. The result was decades of war over the ownership of the

resources of the Western Hemisphere."

The Texan worries that similar confrontations may be built into today's international space law. "Unless we develop a practical law governing activities in space, we shouldn't be surprised when war breaks out over who has the right to develop space resources," he warns.

Current space law prohibits the "occupation" of space. Such permanent establishments as space stations and lunar mining facilities would therefore violate international treaty. The geosynchronous orbits a solar-power-satellite (SPS) system would require — now nearly filled by military and communications satellites — also violate this prohibition.

Partly because of this ban, there is no accepted way to assign "grazing rights" to orbits in space. Eventually the most desirable orbits will become filled. At that point it isn't hard to imagine that a power with killer satellites might decide to clear private craft out of the positions it needs. Investors would find "range wars" in space a difficult hazard to accept.

But the threat that worries Dula most is already in progress. "The one thing that could stop the development of space by free enterprise would be to outlaw making a profit in space," he says. "The Soviet Union and Third World countries are now attempting this through the Moon Treaty."

The 1967 Treaty of Principles and the Moon Treaty under debate in the United Nations — and signed but not ratified by the United States — proclaim that the resources of space are the common heritage of all mankind. This is a lofty-sounding principle, but it is vague. Neither treaty spells out exactly how this heritage is supposed to be divided.

If ratified, the Moon Treaty would forbid private ownership of minerals on the moon and on other "celestial bodies." But without ownership, there can be no profit. And as Dula points out, "free enterprise does not move where there is no profit."

"Unfortunately, international space law is based on academic and dangerous treaties designed to chill the development of free enterprise in outer space. Space may be the common heritage of all mankind in a philosophical sense, but the resources actually developed by private industry must belong to the entrepreneur who had the vision and took the risk to obtain the benefit."

And that risk, incidentally, should all be on the company's shoulders. Yet the treaty on international liability for damage caused by space objects states that national governments have infinite liability for damage caused by objects launched from their country.

"Pan American World Airways flies everywhere in the world," Dula reminds us, "with vehicles bigger and heavier than the space shuttle. Their planes would do more damage if they crashed. Yet no one seems upset because Pan Am stands liable for its own damage." The attorney feels that

CONTINUED ON PAGE 94

COUNSELOR

CONTINUED FROM PAGE 51

space vehicles should be covered by current insurance law just as air transport is. "There's no reason for the government to take on that kind of liability for private companies," he says. "But by signing that treaty, the U.S. government has gratuitously done so."

Dula's list of legal obstacles to space development is a long one. Look at SPS units, for instance. They are technically feasible and might be economical if built in space from lunar materials. Dula himself thinks the tangible benefits of an SPS program could restore public support for space development. Yet at every step there are legal questions to be answered. According to international treaty, space vehicles, like ships, must be registered to a single nation whose laws govern the craft in space. For an American spacecraft ferrying workmen to build an SPS system, federal law would become space law. But whose regulations would govern a space station owned by a multinational corporation, manned by people from many countries and building SPS units for several different parts of the world? Here the law is not at all clear.

When the first SPS goes into operation, still more legal questions will emerge. Does the power belong to all mankind or to the corporation that collects it? And once the system makes a profit, must the taxes be divided among all governments to ensure a fair distribution of the benefits from outer space? No one knows.

"Existing space law is extremely vague, and it is stacked in favor of the Soviet Union and the Third World countries," Dula warns. "This trend must be reversed before a viable commercial space industry can evolve."

Dula has been involved with technical issues from the beginning of his career. As a young patent lawyer with the large Houston firm of Butler, Binion, Rice, Cook, and Knapp, he worked for industrial clients in the medical and aerospace fields. He soon saw the need for a new breed of lawyer, one who could devote himself entirely to the legal questions presented by advanced technology.

Dula first established himself as an expert on the legal aspects of medical physics, then became a faculty member at the University of Texas Medical School and the University of Houston's Bates College of Law. During the same period, he served in the American Bar Association's Science and Technology Section, of which he is now chairman-elect.

After conducting studies for NASA and General Dynamics on the prospects for development of private industry in space, Dula opened his practice in aerospace and technical law in December 1979.

Technologically, Dula claims to be five years ahead of the big law firms. His office is equipped with a modern computer system that tracks his clients' legal activities; his legal papers are turned out on a word processor. His big house is cooled by an advanced heat pump that uses far less energy than ordinary air conditioners.

On the same day that Dula formed his law firm, he became secretary-treasurer and general counsel for Eagle Engineering, a small consulting firm he founded with three engineer-managers formerly with NASA. Eagle applies the technical and managerial skills acquired in the space program to problems encountered in business and government. Eagle has designed petrochemical process equipment, has integrated computer-hardware and -software systems, and has performed technology assessments of advanced propulsion systems, the SPS, and ocean-thermal-energy systems.

Dula is also a charter member of the Space Foundation, a group of Houston businessmen working to find opportunities for free enterprise in space. At the International Aeronautics Association's conference in Tokyo last September, Dula showed *The Harvest*, a film produced by the Space Foundation. The film's thesis is that mankind is no longer limited to a single planet and that free enterprise can use presently existing technology to harvest space resources. "It raised a few eyebrows among members of the Socialist delegations, particularly that from the Soviet Union," Dula says.

He also showed slides outlining a technological assessment of the SPS. "I think the SPS presentation demonstrated to the Russians that, given the opportunity, free enterprise can operate in space and return real benefits to Earth."

In 1978 Dula ran as a Republican candidate for the Texas House of Representatives. He jokingly remembers his campaign as having been run on the "space platform." In fact, he ran a rather conventional campaign that stressed strong public schools and a comprehensive regional water plan. He lost, but he made a respectable showing in a heavily Democratic congressional district.

One evening during the campaign, he received a last-minute invitation to speak at a community center. Too short of time to prepare a new talk tailored to his audience, he decided to give his slide presentation on the SPS. "That audience was the most attentive group I spoke to during the campaign," Dula recalls. "And do you know why? Because space presents us with an optimistic view of the future, a future of growth and prosperity."

Dula has promised his wife, Tamea Ann, who is also an attorney, that they'll visit the moon together by the year 2001. If he isn't a lunar judge by then, he doesn't plan to take more than three weeks of vacation to make the trip. ∞

VIEW OF AN INTERNATIONAL CONCERN

Militarization and The Outer Space Treaty— Time for a Restatement of "Space Law"

By GEORGE S. ROBINSON
Smithsonian Institution

For outer space to be a sanctuary from the ever-grinding conflicts on Earth, resolve and teeth should be put into this multinational accord

Disturbing developments are taking place in the arms race regarding the uses of outer space. It seems to me that a number of lawyers and statesmen involved in the ongoing development of international cooperation in space, arms control and disarmament negotiations, and the formulation of "new" space law are turning a blind eye to the extension of Earth-bound warfare technology into space and the impact of this militarism on the Outer Space Treaty of 1967.

This treaty, more properly entitled "Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and other Celestial Bodies," is frequently called the "Mother Treaty" by space lawyers. And quite properly so, since it embodies the international spirit and intent, as well as broad guiding legal principles, of cooperation and restraint in exploring and exploiting space in a more elevated fashion than history characterizes exploration and exploitation on Earth. The Outer Space Treaty reflected the prevailing spirit that space was to be a sort of "sanctuary" from the traditional military and economic competition among nations, and mandated that—

—Space exploration shall be conducted for the benefit of all countries, and shall be the province of all mankind.

—Outer space and celestial bodies cannot be claimed by any country for itself.

—Space research is to be carried out in the interest of furthering international cooperation, understanding, and peace everywhere.

—Outer space may not be used for the placing of nuclear weapons or other weapons of mass destruction, nor shall there be any military bases, installations or fortifications, maneuvers, or weapons testing in outer space.

—Astronauts shall be considered as envoys of mankind and shall be given assistance and protection in their endeavors.

—States, governments and international organizations shall have certain liabilities for activities and accidents arising from space exploration.

—Efforts will be made to avoid contaminating celestial bodies or harming the Earth environment as a result of the introduction of extraterrestrial matter.

—The signatory States must consult with each other when there is reason to believe a planned experiment would cause harmful interference with other activities or interests of the signatories. They must consider requests for visual observations by member states on the basis of equality regarding various activities; the purpose being to encourage international cooperation in space research.

Under this umbrella of good intentions, several treaties and agreements more limited in scope have been negotiated, and others continue to be—among them the Agreement on the Rescue of Astronauts, the Return of Astronauts and the Return of Objects Launched into Outer Space; the Conven-

GEORGE S. ROBINSON has served for the past seven years as assistant general counsel of the Smithsonian Institution. Before that he was legal counsel for the FAA and an international-relations specialist at NASA. He engages in a broad domestic and international law practice and serves as counsel for many of the Smithsonian Institution's scientific research projects. A graduate of Bowdoin College (major in biochemistry), he holds an LL.B. from the Univ. of Virginia Law School and an LL.M. and a Doctor of Civil Laws degree from the Institute of Air and Space Law of McGill Univ. Robinson has written a number of articles and books on space law.

States party to the Treaty undertake not to place in orbit around the earth any objects carrying nuclear weapons or any other kinds of weapons of mass destruction, install such weapons on celestial bodies, or station such weapons in outer space in any other manner.
The moon and other celestial bodies shall be used by all States Parties to the Treaty exclusively for peaceful purposes. The establishment of military bases, installations and fortifications, the testing of any type of weapons and the conduct of military manoeuvres on celestial bodies shall be forbidden. The use of

tion on International Liability for Damage Caused by Space Objects; the Convention on Registration of Objects Launched into Outer Space; and the present efforts dealing with exploitation of the Moon's surface. The most difficult issue—determining precisely what constitutes acceptable military use of space—is arising in the context of a variety of *bilateral agreements* that do not have as guiding terms of reference the positive uses of space reflected in the Outer Space Treaty: for example, the 1972 ABM Treaty limiting the use and capabilities of antiballistic missiles; the Interim SALT Agreement of 1972 limiting the use of certain strategic weapons; the 1963 Limited Nuclear Test Ban Treaty (basically limiting nuclear testing to underground).

Certainly one of the most difficult issues to resolve in negotiating the Outer Space Treaty concerned military activity in space: what activity *should* be prohibited by mutual agreement, and what in fact *could* be prohibited. It was understood and agreed by the Soviet Union and the United States during the negotiations that there would be no broad prohibition of military activities. However, based upon concern with the then-current aggressive capabilities using a space environment, the negotiators carefully formulated Article 4 of the Outer Space Treaty which provides in part that—

> States Parties to the Treaty undertake not to place in orbit around the Earth any objects carrying nuclear weapons or any other kinds of weapons of mass destruction, install such weapons on celestial bodies, or station such weapons in outer space in any other manner... [T]he testing of any type of weapons...on celestial bodies shall be forbidden.

Subsequent to the effective date of the Treaty, and as technological capabilities accumulated at a precipitous rate, critical words and phrases became issues of conflict in determining what is acceptable military activity: for example, precise definitions of "in orbit," "weapons," "*mass* destruction," "*celestial* bodies," and "or *station* such weapons...." Article 4 has been debated extensively in attempts to reach mutual agreement on whether certain advanced space technologies having both passive and aggressive military uses are exempted

from, or prohibited by, the Outer Space Treaty. Even the term "peaceful" has evoked several interpretations among practitioners of international law: non-aggressive, no military personnel, no hostile potential, strictly civilian personnel and potential, and the like. In any event, since 1967 new technologies and tactical philosophies have precipitated new concepts and vocabularies not anticipated in the language and provisions of the Outer Space Treaty or other international law existing at that time.

Some of the broader questions raised by Article 4 of the Treaty include these:

- Why restrict the prohibition against testing weapons only to celestial bodies?
- Are celestial bodies limited only to natural bodies or do they include synthetically fabricated platforms, such as the Shuttle and future large space habitats?
- Does the phrase "nuclear weapons or any other kinds of weapons of mass destruction" include component parts of an Earth-based weapons system, such as navigation, communications, and intelligence-gathering satellites, as well as anti-satellite weapons? If such components are not considered weapons of mass destruction, are they adequately covered by other existing international law which properly expresses *the spirit and intent* of the Outer Space Treaty regarding the "sanctuary" nature of space?
- Is there any reasonable way to distinguish between defensive and offensive military uses of space in the legal context of the right of nations to undertake actions of self-defense? And what constitutes the right to take defensive action—hostile or threatening behavior of another nation?

In terms of scientific research for "peaceful purposes," it is obvious that what is peaceful for one purpose may not be for another, and the problems surrounding *verification* of an item or activity as peaceful becomes a critical and extremely difficult issue to resolve. In fact, I see no effective legal definition distinguishing between "peaceful" and "hostile or threatening" military space activities until some overt hostile act actually has occurred. To date, verification has been considered a technological problem. Effective measures for forcing public disclosure of proposed activities have not been emphasized as viable substitutes for technological verification, nor has the increasing effectiveness of broad public opinion been considered as a workable sanction against Treaty violators, or would-be violators.

History shows us that diplomatic positions backed by military capabilities rest on prevailing perceptions of reality by policy makers, and do not flow from slavish commitment to transcending principles of peaceful good will, such as those embraced in the Outer Space Treaty. Various multilateral treaties and bilateral agreements notwithstanding, the United States and the Soviet Union are working on their respective game plans for space warfare. "Despite wishful thinking to the contrary," asserted Gen. Jacob E. Smart (Ret.) in the Fall 1974 issue of *Strategic Review*, "man is and promises to remain an aggressive, combative creature. We fear, we hate, we fight one another. Until we remove causes of fear and hatred and correct the conditions which prompt us to arm ourselves, we have no choice but to prepare to defend ourselves against attack in whatever form and through whatever media attacks may come. Today and henceforth the United States must be prepared to defend itself against aggression *in* space and *from* space. We cannot surrender the 'high ground' without contest."

There continue to be individuals who feel that one way to correct the conditions that cause us to arm ourselves is to substitute energies of a combative nature with energies needed for competitive space exploration and exploitation for the peaceful benefit of all humankind. The spirit, intent, and language of the Outer Space Treaty reflect that sentiment.

However, in the philosophic context of General Smart's remarks, it is recognizably necessary to re-evaluate from time to time what the international community perceives to be essential for world peace and security, including military capabilities in space. But must they be re-evaluated in the framework of the Outer Space Treaty, or is it proper to interpret that document through negotiations on arms control and disarmament among limited parties? Unfortunately, much of the legal interpretation of the Outer Space Treaty relating to military activities is taking place outside that document, principally on a bilateral and regional basis, among the superpowers.

The history of these limited negotiations underscores the difficulty of achieving workable legal definitions of "weapons" and "peaceful" or "aggressive" activities in space. It may well be that to achieve *peaceful* cooperation in space the prohibitions in the Outer Space Treaty of weapons of mass destruction must be expanded to include *all integral space components of a weapons system located primarily on Earth's surface.* If that amounts to disarmament, well, is not that the second objective of arms-control negotiations.

To determine, legally, whether the Treaty was intended to serve such a broad prohibition, it is essential to go behind the actual language and evaluate the spirit and intent of that document.

The Outer Space Treaty was negotiated under the

auspices of the United Nations and its Committee on the Peaceful Uses of Outer Space, the Legal Subcommittee, the First Committee, and the General Assembly. As far as the United States is concerned, the official negotiations were set in motion by a proposal offered by President Lyndon B. Johnson on May 7, 1967, that would ensure the Moon and other celestial bodies would be explored for *peaceful purposes* only. "I am convinced," stated the President, "that we should do what we can—not only for our generation, but for future generations—to see to it that serious political conflicts do not arise as a result of space activities." Not only was President Johnson concerned that space be explored for peaceful purposes *only*, but also that space likely would be used for warfare if a firm prohibition with the heaviest moral sanction was not included in any treaty encompassing this principle. The scientific and material benefits to mankind of a new and promising frontier he clearly viewed as secondary objectives.

In a May 9, 1966, letter to Kurt Waldheim, then chairman of the UN Committee on the Peaceful Uses of Outer Space, requesting an early convening of the legal subcommittee of the Committee on Outer Space to consider a United States draft space treaty, UN Ambassador Arthur J. Goldberg emphasized that UN "Resolution 1721, of December 20, 1961, set forth the essential legal principles applicable to outer space in an enlightened fashion that *has no precedent in any previous age of exploration.*" [Italics added.] Again, it was clear that the United States did not wish to give the appearance that it considered this simply "treaty business as usual."

In a May 30, 1966, letter to the Secretary General from Soviet Ambassador to the UN, N. Fedorenko, a statement by USSR Minister for Foreign Affairs Andrei Gromyko was included which explained the Soviet Union's view on negotiating an outer-space treaty: i.e., "to prohibit the use of the Moon and other celestial bodies for military purposes would be a major step [towards complete disarmament]... and would be calculated to ensure peace on Earth and the security of peoples." The entire tenor of the letter was one of peaceful uses to protect people on Earth—not just in space, but particularly on Earth.

Negotiators hammered out the basic principles of the Outer Space Treaty with great care and difficulty to reflect the noblest intent of the civilized world. The apparent underlying presumption of the United States at the time was that, especially amidst the euphoria of an unfolding new frontier, the "peace image" had not failed as an objective and methodology for establishing reasonably harmonious relations among nations on Earth.

Now the rapidly growing use of "near space" for military purposes presents lawyers and statesmen with a pressing issue: are the United States and the Soviet Union on the verge of massive violations of the Outer Space Treaty, beyond the clear prohibition against weapons of mass destruction? Just because one class of weapons was specifically prohibited based on existing technology in 1967 does not mean that all other weaponry and components of weapons systems would be countenanced by the Treaty.

Most official interpretations and negotiations relating to military activities in space are constrained by complicated policies of governments seeking to secure innumerable economic, ideological, political and military positions. To the professional diplomat and soldier, the basic question remains, "Does military activity in space retard or increase the chances of war on Earth?" Consequently, any objective evaluation of the Outer Space Treaty and its applicability or current effectiveness with respect to the growing military occupation of space must be made outside these military and political influences.

The International Astronautical Federation (IAF) would be an excellent forum for such an evaluation. The International Institute of Space Law, under the aegis of the Federation, cannot analyze effectively the technology, policies, and issues by itself, isolated from other technical committees and associations of the Federation. Serious considerations should therefore be given to devoting a large segment of one of the Federation's annual congresses to analyzing the effectiveness of the Outer Space Treaty regarding the pattern of growth of military activity in space.

If space is to remain some reasonable form of sanctuary from the conflicts of Earth, teeth and resolve should be put into this principal multilateral document to preserve the sanctuary concept. As it now stands, unilateral actions and bilateral negotiations among the superpowers are disfranchising all the other parties to the Outer Space Treaty from effective involvement in resolving the issue of limits to militarization of space.

If the Treaty is determined, say, by the IAF to be inadequate to safeguard the sanctuary concept and the dedication of space to peaceful purposes and the welfare of all peoples, it could pass a strong resolution calling on the United Nations to undertake formulation of an appropriate protocol or amendment to the Treaty. In this way the IAF would help reestablish the Treaty and the United Nations as the proper document and forum for determining what is a peaceful use of outer space, and in doing so would help reestablish informed public opinion as an effective sanction. ■

The Moon Treaty and Private Enterprise

By DELBERT D. SMITH
Attorney at Law

Although nothing in the treaty specifically limits private activities in space, several openings for later restrictions need closing by Senate attachments

Reproduced from Smith, Delbert D. The Moon treaty and private enterprise. Astronautics & aeronautics, v. 18, Jan. 1980: 62-65 with permission of the copyright holder Aerospace America.

DELBERT D. SMITH, an attorney specializing in international law, particularly satellite communications, serves on the AIAA Legal Task Force. He has written five books—the latest *Space Stations: International Law and Policy*—and many articles for legal periodicals, and edits *Satellite Communications* magazine. He received a Master's degree and J.D. from the Univ. of Wisconsin, Ph.D. in international law from Cambridge Univ., and the Diploma in Public International Law from the Hague Academy of International Law.

The Agreement Governing Activities of States on the Moon and Other Celestial Bodies (Moon Treaty)[1] would be, when adopted and opened for signature by the UN General Assembly, a significant step in the development of international law on outer space. Provisions reaffirm the freedom of exploration and use of outer space and reaffirm recognition of private activities there.

Rights and obligations established or confirmed by the agreement include the rights of nations to collect and remove samples from the Moon for scientific investigation,[2] and to use substances on the Moon and other celestial bodies to support scientific missions,[2] the obligations to safeguard human life,[3] offer shelter to those in distress,[4] offer humanitarian emergency use of lunar facilities to others,[5] periodically notify and give specified information to the UN about lunar missions,[6] and notify the UN in advance of radioactive materials use.[7] The treaty also calls for designating areas of special scientific interest as international scientific preserves.[8] Such measures will help promote space exploration.

Nevertheless, some critics have claimed several articles would inhibit, if not prevent, commercial activities on the Moon and other celestial bodies. As a matter of strict legal interpretation, the agreement would not. The text reaffirms the right of nations to use the Moon, and the term "use" in outer space law has not thus far been interpreted as prohibiting commercial activities. However, the Moon Treaty's anticipation of an international regime to govern the exploitation of the natural resources of the Moon[9] leads some persons to argue that future interpretations and negotiations will inevitably work against the interests of the United States.

Let us look at the background to this issue—conditions surrounding private use and exploitation, and the conceptual basis of "common heritage of mankind"—and the likelihood of a moratorium on exploiting natural resources.

Article XIV recognizes private activities on the Moon and other celestial bodies in these words: "States Parties shall ensure that non-governmental entities under their jurisdiction shall engage in activities on the Moon only under the authority and continuing supervision of the appropriate State Party."

This language closely follows that of Article VI

of the Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies (1967 Outer Space Treaty),[10] which states: "The activities of non-governmental entities in outer space including the Moon and other celestial bodies, shall require authorization and continuing supervision by the appropriate State Party to the treaty." Furthermore, it has been generally accepted that the Outer Space Treaty furnished the conceptual basis for subsequent agreements reported out by the UN Committee on the Peaceful Uses of Outer Space (COPUOS). Thus when the committee prepared the Moon Treaty it probably did not intend to modify the basic tenets of the Outer Space Treaty.

The United States further clarified this point by stating its position before the COPUOS as follows: "In regard to the matter of the Moon Treaty's relation to the 1967 Outer Space Treaty, discussion in the Committee resulted in no statements to the effect that the Moon Treaty is intended to weaken in any way the provisions of the 1967 treaty. In this light, and taking into account the last two preambular paragraphs of the Moon Treaty, there was a feeling that a non-derogation provision would be superfluous. Our delegation accepted this view and joined in the consensus on the Moon Treaty *with the understanding that it in no way derogates from or limits the provisions of the 1967 Outer Space Treaty.*"

U.S. Ambassador Petree made the same point before the UN when he said, "The draft Moon Treaty is based to a considerable extent on the 1967 Outer Space Treaty. Indeed, the discussion in the Outer Space Committee confirmed the understanding that *the Moon Treaty in no way derogates from or limits the provisions of the 1967 Outer Space Treaty.*"[12]

Moreover, Article II of the Moon Treaty states, "All activities on the Moon, including its exploration and use, shall be carried out in accordance with international law." Since the 1967 Outer Space Treaty makes up a major part of international law on outer space, to make a change the Moon Treaty would have to contain specific language stating the alteration. Article II's reference to international law has no such qualification.

How unrestricted is the right of use? Article I of the 1967 Outer Space Treaty says, "Outer space, including the Moon and other celestial bodies, shall be free for exploration and use by all States without discrimination of any kind, on a basis of equality and in accordance with international law."

Similarly, Article XI(4) of the Moon Treaty says, "States Parties have the right to exploration and use of the Moon without discrimination of any kind on a basis of equality and in accordance with international law and the terms of this Agreement."

The word "use" should have the same meaning and implications under both treaties. Thus, since commercial activities have been allowed under the terms of the 1967 Outer Space Treaty as a type of "use" of outer space, they should also be permitted under the Moon Treaty.

However, the Moon Treaty attempts to deal specifically with a category of use—exploitation of natural resources—and an issue arises as to whether the treaty circumscribes this particular type of use. Article XI(5) of the treaty says, "States Parties to this agreement hereby undertake to establish an international regime, including appropriate procedures, to govern the exploitation of the natural resources of the Moon as such exploitation is about to become feasible."[13] Leaving aside the definition of "natural resources," "exploitation" would require definition before one could determine whether, and if so, to what extent, "exploitation" is meant as an exception to the general right. The similar meanings of "use" and "exploitation" present a difficulty. "Use" is to convert to one's service[14] and includes a right to profit from the activity. In U.S. law, "The 'use' of a thing means that one is to enjoy, hold, occupy, *or have some manner of benefit thereof* [emphasis added]."[15] Exploitation means the act or process of making use of by application of industry or other means of turning to account.[16]

The Moon Treaty speaks of exploitation only in connection with exploitation of the natural resources of the Moon and other celestial bodies. Since the difference between "use" and "exploitation" does not depend upon making profits, points of distinction remain to be determined. This may prove difficult, since the two treaties clearly establish the right of use "without discrimination of any kind." At least ten other sections of the Moon Treaty refer to the right of use without any qualification.

Perhaps attaching an understanding to the agreement clarifying the U.S. interpretation of the right of use of outer space would solve the matter. This could be done during consideration of the treaty by the U.S. Senate. Such an understanding or reservation would help insure that whatever legal regime ultimately comes into being will recognize the ability and right of private enterprise to use and exploit the resources of the universe for the benefit of all mankind. In a broader sense, it would sharpen the legal picture on imposition of a

moratorium and the specific impact of "the common heritage of mankind" as well.

Although the word "moratorium" does not appear in the Moon Treaty, a dispute has arisen over whether providing for setting up an international regime implies a hold on exploitation. In a statement before the COPUOS, the U.S. representative pointed out, "The draft agreement...as part of the compromises made by many delegations, *places no moratorium upon the exploitation of the natural resources of celestial bodies, pending the establishment of an international regime* [emphasis added]. This permits orderly attempts to establish that such exploitation is in fact feasible and practicable, by making possible experimental beginnings and, then, pilot operations, a process by which we believe we can learn if it will be practicable and feasible to exploit the natural resources of such celestial bodies."[18]

During the 1979 Session of the Legal Subcommittee of the COPUOS, a language change introduced would have created a moratorium. The change was not made. Ambassador Petree reiterated the above position that there is no moratorium, and also noted that the purposes specified in paragraph 7 of Article XI establish a framework and incentives for such exploitation. "By setting forth now the purposes governing exploitation of natural resources, uncertainty is decreased and both states and private entities may now find it possible to engage in the arduous and expensive efforts necessary if exploitation of the natural resources of celestial bodies is ever to become a reality,"[19] he said.

Article XI(5) states that the parties "hereby undertake to establish" a regime. It states no requirement for a regime before exploitation. Nor does Article XI(5) set a specific deadline for establishing the regime. Rather it refers to the time when "exploitation is about to become feasible." In addition, Article XI(5) references Article XVIII which states that at any time after the agreement has been in force for five years, the Secretary-General of the UN at the request of one-third of the states parties to the agreement and with the concurrence of the majority of the states parties, may convene both a conference to review the treaty generally and a specific conference to consider implementing the provisions of Article XI, para. 5.

When and if negotiations for a regime begin, Ambassador Petree has stated, "My government will...make a good faith effort to see that such negotiations are successfully concluded. Each of the participants in a regime conference will, of course, have to evaluate any treaty that emerges from the conference in the light of its own national interests. For the United States, this would require a conclusion that the treaty is balanced and reasonable and would then, as a constitutional matter, require submission to the Senate for its advice and consent, just as we have sought and obtained advice and consent to United States ratification of the four outer space treaties now in force."[20]

The lack of a provision in the Moon Treaty similar to one introduced by India in 1973—"Exploitation of the resources of the Moon and other celestial bodies and their subsoil shall not be done except in accordance with the international regime to be established"—also indicates the absence of a moratorium.[21] The White House has expressed a U.S. policy to "encourage domestic commercial exploitation of space capabilities and systems for economic benefits."[22] And the U.S. can be expected to keep up negotiating pressure in support of that policy. Thus a de facto moratorium appears unlikely. If uncertainty remains, the understanding proposed above should include a clarification.

Predictions that an international regime would be unfriendly toward the private sector's developing outer space stem from the history of the Law of the Sea negotiations and the significance some nations place on the phrase "common heritage of mankind."

In Article XI (1), the Moon Treaty says, "The Moon and its natural resources are the common heritage of mankind, which finds its expression in the provisions of this Agreement and in particular in paragraph 5 of this Article." "Common heritage of mankind" has come under discussion for the past decade, but no universally acknowledged definition of the phrase or agreement as to whether it represents a valid "principle" of international law has resulted. Thus, to avoid the lack of agreement over what the phrase means, drafters of the Moon Treaty linked it to the provisions of the agreement and to a yet to be established international regime, the purposes of which are set forth in Article XI(7). Therefore, any meaning assigned to the phrase in other international law does not automatically apply to the Moon Treaty. Any attempt to expand "common heritage" beyond an ideal of providing nations with nondiscriminatory access to the resources of outer space will probably necessitate an intensive review by the United States.

Article XI(7)'s purposes of a future international regime recognizes that "equitable sharing...in the benefits derived from ...[natural] resources" must give special consideration to "the efforts of those

countries which have contributed either directly or indirectly to the exploration of the Moon" as well as to "the interests and needs of the developing countries." Such international cooperation exists today in the practical applications of outer space, particularly in Intelsat and Inmarsat, where "those states who have expended large resources, either public or private, to develop space systems to exploit these applications have equitably shared the benefits with the international community."[23]

If a question remains on the interpretation of the "common heritage of mankind" or "equitable sharing," once again an understanding or reservation would seem the best course.

The world is proceeding toward the codification of the international law on outer space. In the course of codification the U.S. has found itself dealing with controversial concepts. One of the broader questions it must face is how to deal with specific provisions of an agreement without isolating itself and hampering U.S. private participation in international space system development and operations in communications, remote sensing, and related areas. Understandings and, if necessary, reservations to specific articles in agreements may be a desirable first step.

Since the U. S. introduced the "common heritage" language in 1972, it should expend effort on determining whether or not the concept requires supporting private involvement and operations in outer space. Issues over "sharing," "equity," "international regimes," and "common heritage" will probably arise many more times in the Eighties. The U.S. should begin developing arguments to support its interpretations of these concepts at a future international regime conference or during deliberations on future international treaties. At a minimum it should bring together the various U.S. interests, organizations, and groups involved in outer space to agree upon principles.

The practical implications of international law of outer space are being realized when it is still possible not only to balance various interests, but to create a conceptual basis to benefit both the U.S. and all mankind.

III. SPACE EXPLORATION AND DEVELOPMENT: SCIENTIFIC AND COMMERCIAL

A. Policy and Economics

Reproduced with permission of the copyright holder from Logsdon, John M. U.S.-European cooperation in space science: a 25-year perspective. Science, v. 223, Jan. 6, 1984: 11-16. (c) 1984 American Association for the Advancement of Science.

U.S.-European Cooperation in Space Science: A 25-Year Perspective

John M. Logsdon

Summary. In the past 25 years, the National Aeronautics and Space Administration has engaged in a range of cooperative activities in space with other countries and international organizations, most of the scientific interactions being with Europe. The character of U.S.-European cooperation in space science is changing as a result of the increased maturity and level of space capability which Europe is bringing to the partnership; the consequent addition of a competitive dimension to the relationship; the increasing cost of space science missions; and the relative scarcity of funds available for space science. A number of issues flow from the current situation, but in general the outlook is for continued productive cooperation between the United States and Europe in space science.

In the 25 years that the United States has had a government space program, international cooperation has been one of its major themes. An objective of the National Aeronautics and Space Act of 1958, which was the charter for the civilian space program and which established the National Aeronautics and Space Administration (NASA), was "cooperation by the United States with other nations and groups of nations in work done pursuant to the Act and in the peaceful applications thereof" (*1*). Armed with this legislative mandate, with presidential and congressional support for a U.S. civilian space program which emphasized openness and scientific objectives, and with already existing patterns of cooperation in space science, NASA has since its inception conducted an active program of international partnership.

In space perhaps more than in most areas of international science, it has been the policies and initiatives of a government agency and its top officials, rather than those of the scientific and technical community, which have established the U.S. attitude toward cooperative undertakings. Although NASA's international programs have involved the Soviet Union, Canada, Japan, and various developing countries, its primary cooperative partner has been Europe—both individual European countries and the various European space organizations which have existed over the past two decades. Table 1 suggests the dominance of U.S.-European interactions in the overall record of NASA's most important cooperative programs.

The U.S.-European partnership in space science has been, on the whole, remarkably successful, in terms of cooperation both between the United States and individual European countries and between the United States and Europe's multilateral space science agencies: the European Space Research Organization (ESRO) and its successor the European Space Agency (ESA). Projects such as Ariel (United States–United Kingdom), Helios (United States–Federal Republic of Germany), Infrared Astronomical Satellite (United States–United Kingdom–Netherlands), International Ultraviolet Explorer (United States–United Kingdom–ESA), and International Sun–Earth Explorer (United States–ESA) are just a few of the major scientific undertakings which have benefited from U.S.-European collaboration. This record of success must be kept in mind in evaluating any past and current stresses in the cooperative relationship.

As the U.S. space program enters its second quarter-century, there are significant changes in U.S.-European cooperation; the major reasons for these changes include: the increased maturity and level of space capability which Europe is bringing to the partnership; the consequent addition of a competitive dimension, both in scientific and economic terms, to the relationship; the increasing cost of space science missions; and the relative scarcity of financial resources available on both sides of the Atlantic for space science.

Last fall saw the first flight of Spacelab, an orbital facility for manned scientific experimentation which was developed by Europe at a cost of approximately $1 billion; Spacelab is designed only for use with the U.S. space shuttle and reflects the intimate character of continuing U.S.-European collaboration. At the same time, Europe has developed its own launch capability in the Ariane series of expendable boosters and is using the autonomous capability not only to launch its own spacecraft but also to compete with the space shuttle for other launch contracts. European countries are also developing satellites for Earth observation and communications and exploring the potential of space manufacturing, with the objective of competing with the United States for economic payoffs from space.

Further scientific cooperation in space between the United States and Europe will occur in this mixed context of collaboration and competition. The state of that cooperation is vigorous, as both the United States and Europe continue the fascinating adventure of exploring the nature of the solar system and the cosmos which is made possible by space technology.

John M. Logsdon is director of the Graduate Program in Science, Technology, and Public Policy, George Washington University, Washington, D.C. 20052.

Origins of U.S. Cooperative Programs

As the late Homer Newell, one of the U.S. pioneers in space science and an early and strong advocate of international cooperation in space, has noted, "with roots in the International Geophysical Year, which had already generated a lively interest in the potential of satellites for scientific research, one might argue that the appearance of an international component in the NASA space science program was inevitable" (*2*). The International Geophysical Year, organized under the sponsorship of the International Council of Scientific Unions (ICSU), was an 18-month (July 1957 to December 1958) effort involving 66 countries, some 60,000 scientists, and the expenditure of hundreds of millions of dollars; both the Soviet Union and the United States agreed in 1955 to launch scientific satellites as part of IGY activities.

There was in place at the very start of the space age, therefore, a nascent international community of scientists who saw space technology as providing exciting opportunities for extending and expanding their investigations. This community was quick to press NASA to keep its program open to international involvement. The pressure was congenial, since one reason the United States had decided to house its major space activities in a separate, civilian government agency was to present to the world an image of peaceful intent and open style: this was in deliberate contrast to Soviet space activities, which were controlled by the military services and conducted with great secrecy. There were those in 1958 who argued that the U.S. space program should be under military control and not opened to international cooperation because "the tools of space research—rockets, radio, radar, guidance, stabilization—were all common to both the military and to science. Even the scientific objectives . . . were of interest and possible value to the military" (*3*, p. 5). Added to this "dual use" character of space technology and some areas of space science was the role of space achievement as an area for superpower political competition, particularly after the United States launched the Apollo program in 1961. Thus scientific activity involving the use of space systems took place in a highly charged political and military environment. By carefully defining the conditions under which cooperative activities would be initiated and carried out, NASA was able to conduct an international program which has been relatively free from distortion for political purposes and from limitations because of military sensitivities. Even so, with respect to space cooperation "a clear duality dogs both the history and the prospects of international partnerships" (*3*, p. 6).

NASA Guidelines and Objectives for International Cooperation

When NASA announced to ICSU's Committee on Space Research (COSPAR) in March 1959 that it would assist COSPAR members in launching scientific experiments and satellites, the agency had already under development a set of policy guidelines for such cooperation. Those guidelines have survived periodic reexamination and remain in force today. They reflect "conservative values" (*3*, p. 32) with respect to the conditions under which cooperation is desirable; shaping those values were both the recognition of the political significance of space activities and the strong personalities of individuals such as Newell and Arnold Frutkin, who directed NASA's international program from the agency's earliest months until the mid-1970's.

The essential features of NASA guidelines are (*4*, p. 18):

- Cooperation is on a project-by-project basis, not on a program or other open-ended arrangement.
- Each project must be of mutual interest and have clear scientific value.
- Technical agreement is necessary before political commitment.
- Each side bears full financial responsibility for its share of the project.
- Each side must have the technical and managerial capabilities to carry out its share of the project; NASA does not provide substantial technical assistance to its partners, and little or no U.S. technology is transferred.
- Scientific results are made publically available.

A key feature of NASA's cooperative efforts is that "while NASA has international programs, it does not fund *an* international program." Rather, "funding for international projects must come out of the NASA program offices," and "for an international approach to a project to be undertaken it must not only contribute to achieving the goals of the interested program office, but it must be considered to be among the best approaches to achieving these goals (*5*, p. 68). This emphasis on technical soundness and scientific merit has been a consistent feature of the U.S.-European cooperation over the past 25 years, whatever other objectives are sought through such cooperation. As one perceptive analysis notes, "although NASA recognizes possible political benefits from achieving utilitarian goals, NASA's cooperative programs are justified almost entirely on technical and scientific grounds, both within and outside" the agency (*4*, p. 49). The objectives of NASA's international programs can be grouped as shown in Table 2.

While the priority given to these various objectives has varied with time and mission opportunity, at the core has been a policy that permitted this country's closest allies to become involved in the U.S. space effort. Indeed, some have criticized NASA for making possible such participation, at minimal cost, in an effort paid for almost entirely by U.S. taxpayers: "benefit, know how and opportunity were shared to an extent that was entirely unprecedented where an advanced technology was involved, particularly one with such strong national security implications" (*6*, p. 74).

Evolution of U.S.-European Cooperation in Space Science

During the "golden age" of the U.S. space program, from the beginning of the Apollo buildup in 1961 through its peak in the 1965–1966 period, NASA's international activities grew rapidly along with the rest of the agency's efforts. Before the first Apollo 11 moon landing in July 1969, nine European spacecraft had been launched by the United States, and substantial momentum had built behind European involvement with the United States in space experimentation. This momentum has carried through to the current day, but, as one top-level participant has commented, "when resources abound and opportunities are plentiful, a cooperative attitude abounds. . . . When the resources and opportunities shrink, . . . altruism takes a back seat and . . . scientists take a more selfish view of cooperation" (*7*, p. 38).

Several factors have influenced the evolution of U.S.-European space cooperation in the period since 1970. In no particular order of importance, they are:

- Shrinkage in the NASA budget overall in the post-Apollo era. The space science budget came under particular pressure as the share of overall resources going to shuttle development increased. This meant fewer science missions and more competition among U.S. scientists to get their experiments on the missions which were approved.
- A broadening of NASA's interna-

tional program to encourage European participation, not only in science missions, but also in developing large space systems including manned space flight elements.

- Evolution of the 11-member European Space Agency, founded in 1975, into an effective entity. ESA has carried out a successful science program of its own and has managed several space applications projects and two major hardware development programs, Spacelab and Ariane. The national space programs of France, Germany, Italy, the Netherlands, and the United Kingdom, with differing emphasis, are also vigorous.
- More recently, growing concern in the United States that cooperative undertakings in space, including space science, could serve as vehicles for unwanted transfer of militarily or economically sensitive U.S. technology to other countries.

While Europe has continued to cooperate with the United States, it has also become a formidable competitor in various categories of space applications and in some fields of space science. Europe is now a very capable actor in space, and it could become more difficult for the United States to develop cooperative projects on its preferred terms. While the United States remains the partner of choice for ESA and individual European countries, existing and potential cooperation with the Soviet Union and Japan provides an alternative. There is now the possibility of a global division of labor and cost in space science, and this makes the task of planning and getting agreement for major space science projects both challenging and full of opportunities.

There has been an undercurrent of ambivalence among U.S. space scientists and NASA managers about European involvement in NASA missions, whatever the stated policy. For one thing, "always the U.S. side was slightly constrained by fear that foreign collaborators . . . might not fulfill their commitments." This concern had diminished over time; "in the few cases where serious delays occurred, as in the Solar Polar project, it was more often the United States that was responsible. . . . Had NASA personnel not been susceptible to the then universal belief that other nations necessarily lagged behind the United States in technological capability, the policy of collaboration in space matters could almost certainly have been more rewarding" (*6*, p. 71). For another, when foreign experiments have been selected by NASA, some U.S. scientists have raised the question of whether the foreign experiment was selected over a competing U.S. experiment on the basis of merit or whether it was selected because it would be provided to NASA free of charge (*7*, pp. 38–39). Another reservation with respect to foreign participation has been that "by selecting a high-technology experiment, the United States encourages development of the industrial base in the foreign country which will contribute to a decreased United States competitive position in world trade" (*7*, p. 39). Yet another concern is that management of a U.S. space science project is greatly complicated by the need to integrate the experiments or other contributions from a foreign partner.

Table 1. Patterns of international cooperation, 1958 to 1983, including past and currently approved cooperative projects (*17*).

Participant	Cooperative spacecraft projects	Experiments with foreign principal investigators
Total	38	73
Total, Europe	33	52
European Space Agency	8	1
France	2	17
Federal Republic of Germany	7	11
United Kingdom	7	18
Italy	6	1
Netherlands	2	3
Spain	1	
Belgium		1

While growing European capability has muted concern about the first of these factors, it has also created healthy competition among all space scientists for access to orbit and beyond for their experiments. European scientists have always been able to propose experiments on U.S. missions, but U.S. scientists are only now gaining a reciprocal opportunity to serve as principal investigators for experiments on ESA missions.

A major attempt to engage Europe with NASA's technology development efforts took place in the 1969–1973 period, as NASA itself sought to gain presidential and congressional approval of an ambitious post-Apollo program of manned space flight. The negotiations on European participation in the program were much more political in character than prior (and subsequent) negotiations on cooperative undertakings in space science. This post-Apollo experience, perhaps justifiably, has left a lingering "bad taste" in Europe. NASA's objective was "to stimulate Europeans to rethink their present limited space objectives, to help them avoid wasting resources on obsolescent developments [a reference to European plans to develop an independent launch capability], and eventually to establish more consider-

Table 2. Objectives of NASA's international programs.

Scientific/technical

"Increasing brainpower working on significant problems and expanding scientific horizons by making space an attractive field for research" (*4*, p. 17).

Shaping the development of foreign space programs to be compatible with the U.S. effort "by offering attractive opportunities to 'do it our way' " (*4*, p. 50).

Through such influence, limiting funds available in other countries for space activities which are competitive or less compatible with U.S. interests.

Obtaining unique or superior experiments from non-U.S. investigators.

Obtaining coordinated or simultaneous observations from multiple investigators.

Increasingly, making available opportunities for U.S. scientists to participate in space science missions of other countries or regions.

Economic

"By sharing leadership for exploring the heavens with other qualified space-faring nations, NASA stretches its own resources and is free to pursue projects which, in the absence of such sharing and cooperation, might not be initiated" (*18*); NASA estimates getting over $2 billion in cost savings and contributions from its cooperative programs over the past 25 years (*5*, p. 69).

"Improving the balance of trade through creating new markets for U.S. aerospace products" (*4*, p. 17).

Political

Creating a positive image of the United States; "the U.S. program of cooperation in space reaches a scientific, technical, and official elite in the struggle for minds" (*3*, p. 73).

Encouraging European unity; the U.S. space program "lends itself admirably to cooperation with multilateral institutions in Europe" (*3*, p. 78).

Reinforcing the image of U.S. openness in contrast to the secrecy of the Soviet space program; "when NASA was organized . . . the keystone of Government space policy was to give dramatic substance to the claim of openness—and, at the same time, to seek credibility for the nation's assertion that it entered space for peaceful, scientific purposes. This was done . . . most importantly, by inviting foreign scientists to participate extensively and substantively in space projects themselves" (*6*, p. 70).

Using space technology as a tool of diplomacy to serve broader foreign policy objectives.

able prospects for future international collaboration on major space projects" (*8*).

A basic problem in this case was that NASA could not deliver what it was promoting in Europe. NASA's post-Apollo ambitions included a space station and a fully reusable space shuttle, and the agency continued to solicit European involvement in these programs even when their approval by the President was very uncertain. Indeed, within the United States NASA tried to use the prospect of collaboration with Europe as a selling point for approval of these programs. When only the space shuttle remained as a potential program, NASA encouraged Europe to consider developing both components of the shuttle orbiter and a separate major project, a reusable orbital transfer vehicle called a space tug. However, NASA was forced to withdraw these offers at the last minute when the Air Force, whose support was needed for shuttle approval, objected to European development of essential elements of the Space Transportation System; when concerns regarding excessive transfer of propulsion technology were raised; and when some in NASA became concerned about the safety implications of placing a cryogenically fueled tug in the shuttle payload bay. Finally, NASA offered Europe the comparatively simple and less expensive task of developing a "research and applications module" to fit into the shuttle payload bay; this is what became the Spacelab project.

By this time, Europeans were rather skeptical about NASA overtures, but they (particularly Germany) had also become so eager to embark on manned flight activities that they agreed to develop the Spacelab system under what in hindsight have been seen as unfavorable terms; the first set of flight hardware, developed with European funds, was to be transferred to NASA, and after an initial joint NASA-ESA mission which included flying a European payload specialist, Europe was to pay for future shuttle-Spacelab flights. NASA agreed to buy a second set of flight hardware from Europe, but "a significant segment of the European space community believes that the United States is getting the lion's share of the benefits from Spacelab" (*9*).

European space officials have described themselves as "stupid" in accepting the U.S. terms for involvement in its post-Apollo program and believe that such acceptance stemmed from lack of confidence in European capabilities and from a belief that only through cooperation with the United States could those capabilities be improved. Now, having brought both Spacelab and Ariane to success, Europe has much more confidence in its ability to chart its own future in space and it will be a more demanding participant in negotiations with the United States over cooperative ventures (*10*).

European confidence in the United States as a cooperative partner was shaken in the spring of 1981 when the United States announced, without prior consultation with its European partners, that it was canceling a U.S. spacecraft which was part of a two-spacecraft International Solar Polar Mission (ISPM). This withdrawal caused vigorous protests not only from European space officials but also from representatives of foreign ministries (*11*). In this case, "NASA's success in international participation became a political liability" (*5*, p. 69); NASA was forced to reduce funding in a major space science mission, and all three existing large missions—the Space Telescope, the Galileo mission to Jupiter, and the Solar Polar mission—had major European involvement.

There is general agreement that the ISPM affair was handled clumsily, and both the United States and Europe have moved beyond it, although European officials are not beyond using U.S. guilt over the incident as a bargaining chip in U.S.-European negotiations on future collaboration.

In summary, U.S.-European cooperation in space has become a much more complex enterprise in the last 10 years as both U.S. and European space efforts matured. While the balance sheet in that enterprise remains strongly on the positive side for all participants, competition and conflict have joined collaboration as hallmarks.

Current Issues in U.S.-European Cooperation

The major U.S. science missions now approaching launch, the Space Telescope and the Galileo spacecraft to Jupiter, have major participation by Europeans, and it is anticipated that there will be continuing cooperation as the United States and Europe begin new missions. The following are some of the issues which will influence the development of that cooperation.

Closer coordination and collaboration in planning and conducting space science efforts. The task of maximizing the scientific payoff from the resources available in the United States and Europe (and other countries) for space research is perhaps the key continuing issue in this area. The United States, ESA, and various European countries are all fully capable of undertaking major space science missions on their own, but with limited funds available on both sides of the Atlantic, there is a need to develop a coordinated approach to space science which recognizes the benefits of cooperation and the realities of competition. To date, attempts to do this have primarily involved negotiations from government agency to government agency. There are regularly scheduled meetings between the heads of NASA and ESA and between the space science directors of the two agencies.

The most recent NASA-ESA space science planning meeting took place in June 1983, and the issues addressed exemplify the problems and potential of a coordinated approach to future space science undertakings (*12*). Three areas of cooperation were discussed: (i) infrared astronomy, (ii) solar terrestrial research, and (iii) planetary exploration. In the first of these areas, in essence the United States and ESA "agreed to disagree." The issue under discussion was the next step beyond the highly successful U.S.-Dutch-British Infrared Astronomical Satellite (IRAS) launched in early 1983. Both the United States and ESA have developed future mission concepts, and the two approaches are not compatible. The meeting noted both "NASA's strong interest in collaborating to develop a single major international infrared space telescope facility" (presumably based on the U.S. mission concept) and "the firm commitment of ESA" to its mission. Recognizing that "the difference in orbit and launch vehicle restrict any major hardware collaboration," NASA and ESA agreed to coordinate the planning for the separate missions to maximize their complementarity and overall scientific return, but also for the time being abandoned hope of a joint mission.

By contrast, an examination of the large number of missions under study in the United States, Europe, and Japan in the area of solar terrestrial physics identified "considerable merit in considering a joint . . . mission"; NASA and ESA established a working group, which will also include Japan, to "loc': for joint missions which can satisfy the main scientific requirements in a cost-effective way." Similarly, NASA and ESA agreed in the planetary exploration area "to identify mutually beneficial opportunities for cooperative missions." In particular, the two agencies are to study a joint

Saturn-Titan probe mission for a 1992 launch. Planetary exploration is one of the areas of international scientific cooperation agreed on at the Versailles-Williamsburg series of summit meetings and is also the focus of attention of a working group of the National Academy of Sciences and the European Science Foundation. A cooperative Saturn-Titan mission, if feasible, would thus be politically as well as technically significant.

Another example of the benefits of a coordinated approach to mission planning in a particular area of science is found in the U.S.-German interaction in x-ray astronomy. A large community of investigators has developed to use the data produced by NASA's High Energy Astronomical Observatory. However, there would be a data gap of a number of years before the next mission in x-ray astronomy were it not for the existence of a German project called *Roentgensatellit* (ROSAT). The United States and Germany in 1982 signed a Memorandum of Understanding for close collaboration in this mission, thus ensuring continuity in the field for U.S. as well as European scientists (*13*).

There is a growing need for the United States, Europe, Japan, Canada, and perhaps eventually the Soviet Union and other space-capable states to work together in space science, from the early stages of developing a mission concept to the joint funding and conduct of various missions. Because of its dominant position in space activities in the free world, the United States in the past has been largely able to shape such collaboration to its own objectives. This situation no longer obtains, and there could be a difficult period of adjustment for this country as the new reality of partnership among relative equals becomes the standard pattern. It may prove advantageous for NASA to engage the U.S. scientific community more intimately in developing its international programs; this could minimize international misunderstandings and perhaps blunt nonproductive and expensive competition. In space science, as in many other areas, the United States is adjusting to the recognition that it cannot be first in everything.

Involvement of non-NASA scientists in shaping international cooperation. "At present, ideas for joint international endeavors are primarily developed at formal meetings between representatives of the various governments. . . . There is a need for a more effective forum which would enable space scientists and managers to exchange ideas informally (*14*). While NASA plans its science programs in close consultation with the external science community, including the Space Science Board (SSB) of the National Academy of Sciences, there is little tradition of SSB involvement in international space science matters. The National Academy is the U.S. member in COSPAR, but that forum has little apparent influence on national space programs. Of course, informal interaction among space scientists in various countries interested in similar scientific problems is a major source of project proposals in both the United States and Europe.

The nearest European equivalent to the SSB is the Space Science Committee (SSC) of the European Science Foundation. This committee has a small budget and has not developed close ties with the European Space Agency. Nevertheless, the SSB and SSC held joint workshops in 1976, 1978, and 1983, and some consideration is being given to establishing standing SSB-SSC working groups in selected areas of space science.

In a separate development, at the initiative of the heads of the European Science Foundation and the National Academy of Sciences, a joint SSB-SSC working group on planetary exploration has been established. The U.S. side of this group is composed mainly of individual scientists who are closely related to NASA's Solar System Exploration Committee.

All these developments may represent initial steps in opening up the process of planning U.S.-European cooperation in space science to more structured participation of nongovernment scientists. As scientific competition among those working in space becomes increasingly international, such involvement may be required to reach agreement on how to coordinate or cooperate in research on major scientific problems.

Access for U.S. experimenters to European science missions. If Europe is to approach parity in influencing the direction of progress in various areas of space science, there must also be a mutuality of opportunity for U.S. and European scientists to participate in the resulting activities. NASA has from the start opened its "Announcements of Opportunity" to all free-world scientists, but ESA and individual European countries have limited access to their scientific missions to European scientists, at least as principal investigators. This policy may have been defensible as a means of developing a European space science community, but NASA is now demanding reciprocity of access. Germany has already indicated its willingness to comply. For the ESA mission to Halley's comet, *Giotto*, nine of the ten experiments have U.S. coinvestigators (a total of 33 individuals); ESA has agreed in principle to open up its future missions to U.S. principal investigators, and a NASA-ESA committee is now studying how best to implement that agreement.

Increasing militarization of space activities. Space technology had its origin in military missile and satellite programs, and there has been continuing attention to ensuring that the international programs of NASA do not provide access to militarily sensitive technology. Now the major U.S. launch system is the space shuttle, which is a national capability used for NASA, Department of Defense, and non-U.S. missions. In this context, "classified operations will be a necessity and are bound to lead to a more restrictive atmosphere, less conducive to international cooperation; tending to lead in the same direction . . . are developments in detector technology and in active atmospheric-magnetospheric experimentation" (*7*, p. 40). It is well beyond the scope of this article to discuss the increasing military interest in various uses of space technology, but if the Department of Defense budget for space, which is already larger than NASA's, continues to grow, there is likely to be an impact on international space science. One possibility is increased international cooperation on defense applications of space among the United States and its North Atlantic Treaty Organization allies. Other areas of scientific collaboration have been able to coexist with military interest in the same scientific area and its underpinning technologies, and this duality has been present in space from the beginning; nevertheless, the changing context of space activity must be of concern to those interested in promoting open international cooperation in space science. In particular, several members of ESA are neutral states which could object to being involved in cooperative activites with the United States which had any hint of military overtones.

Impact of space shuttle on scientific cooperation. The space shuttle is an extremely capable launch system and short-term orbital platform. It offers scientists an environment much different from any previously available in which to design and operate their experiments; there is even the chance to accompany them into orbit. Europe has recognized the shuttle's potential and is designing systems for its own and cooperative space activities which can only be used with the shuttle. These include Spacelab and an ESA-developed unmanned free-flying platform called *Eureca*, scheduled

for a 1987 launch. As the shuttle, Spacelab, and other systems become more familiar to scientists, there will emerge innovative ways to take advantage of these new capabilities.

However, U.S. and European scientists will also share a common problem as they plan their missions for the Space Transportation System; because it is a manned system, the requirements for qualifying payloads to go aboard it and for supporting those payloads with documentation are both demanding and expensive, especially in comparison to similar requirements for unmanned launches. When European scientists began to plan for the use of Spacelab, for example, they "were really shocked by the requirements for testing and documentation and the associated cost of those requirements" (*9*). Europe is continuing to find it difficult to afford to use elements of the Spacelab system for its experiments; the result is that "continuous use of Spacelab by those who built and financed it is not likely" (*15*). Whether the shuttle will prove to be a crucial asset for those planning future science missions or a source of costs which limit the number of missions that are affordable is yet to be determined, but the impact of the shuttle is of crucial importance to U.S. and European space scientists alike.

Possible U.S.-European collaboration on space station. The U.S.-European interaction over a European role in NASA's major post-Apollo programs has colored the whole of transatlantic cooperation in space over the past decade. Similarly, outcome of the just-beginning interactions over European participation in NASA's proposed space station program may affect the overall prospects for European-U.S. collaboration over the next decade or more. This impact could have several dimensions. (First, of course, NASA must get approval to begin such a program.) Europe has been following NASA's planning for the space station quite closely and has carried out parallel studies of options for European participation; in essence, NASA and ESA are already traveling together down a path that could lead to a major European role in an evolving station effort. This early and close involvement is quite different from what occurred in the post-Apollo period and signifies how close the U.S. and European outlooks on space have become.

If, after this start, something intervened to make large-scale collaboration on station development impossible, there would certainly be a ripple effect on other areas of cooperation. On the other hand, a joint decision to move ahead with significant collaboration on the space station would cement the increasingly intimate relationship between the planning and conduct of U.S. and European space activities. While there would still be economic competition and rivalry over scientific achievement, they would occur within a broader cooperative framework.

One rationale for developing a space station and associated infrastructure is to create a research facility in Earth orbit. Just as the existence of the space shuttle and Spacelab will define the conditions for most space science missions in the coming decade, so would the availability of permanent orbital facilities condition the conduct of space science in the 1990's. Thus, it is important to the space science community that any space station which is developed be a congenial base for its experiments, and pressure from U.S. and European space scientists will be important in ensuring that that is the case.

Conclusion

Kenneth Pedersen, NASA Director of International Affairs, has commented that "international space cooperation is not a charitable enterprise; countries cooperate because they judge it in their interest to do so" (*16*). This observation can be extended to the level of individual space scientists; in the 25 years since scientific experiments in outer space became feasible, U.S. and European scientists have found it increasingly in their individual and mutual interest to carry out much of their activity on a cooperative basis. NASA's policies have encouraged and facilitated such cooperation; one result has been the nurturing of a vigorous space science community in Europe as well as the United States.

That community today recognizes the high stakes involved in maintaining effective communication and cooperation across national borders; this appears the only way for space science to thrive. The simple missions have already been flown, resources for space science are scarce, and a coordinated approach to the planning, funding, and conduct of complex science missions makes eminent sense. New ways may be needed to allow space scientists to join with the government organizations through which they function in a collaborative enterprise of cosmic discovery, but in general the outlook for international space science in the coming decades is one of great promise and excitement.

IS THERE PUBLIC SUPPORT FOR SPACE EXPLORATION ?

By Jon D. Miller

In almost every discussion of the space program, conversation eventually turns to the question of whether there is a sufficient level of public support to continue and expand the nation's commitment of public funds for this purpose. This worry is expressed in private conversations with the administrators and engineers at the National Aeronautics and Space Administration (NASA) and by the members and staff of Congress.

On the surface, there is reason both for concern and for some hope. Over the last decade the percentage of

JON D. MILLER is director of the Public Opinion Laboratory and associate professor of political science at Northern Illinois University, DeKalb, Illinois. He is the author of *Citizenship in an Age of Science* (Pergamon Press, 1980) and *The American People and Science Policy* (Pergamon Press, 1983), and is continuing his work in the study of the formation of political attitudes and the translation of attitudes into the policy formulation process.

Reproduced with permission of the copyright holder from Miller, Jon D. Is there public support for space exploration, Environment, a publication of the Helen Dwight Reid Educational Foundation, v. 26, June 1984: 2-35.

Americans who think that the government is spending too much on the space program has declined, and a majority now report that space spending is either "about right" or even too low. That is the good news. At the same time, a substantial number of Americans have some reservations about large public expenditures for space and other "distant" programs when important domestic needs are unmet. The old tension is still there.

Although the aggregate trends appear to be edging toward increased support for space exploration, many engineering and political leaders worry about the stability of this support. More specifically, as the costs of the development of a space station become better understood by the public, some leaders worry that the public will decide the costs of space exploration exceed the advantages and, subsequently, that the recent gains in aggregate public support will erode quickly.

I have been monitoring public attitudes toward space exploration over the last several years, and I believe that the source of much of this concern is a misunderstanding of the nature of public interest in, knowledge about, and attitudes toward specialized issues like the space program. Viewed in the context of the actual channels of public participation in such areas as space exploration or spending, I think that the evidence points to a strong core of support for NASA's programs, the opportunity for expanding the present activist group, and the absence of any organized opposition to the U.S. space program. The following discussion will outline these arguments in more detail.

A Question of Salience

The basic problem in studying public attitudes toward the space program is that space exploration is not a salient topic to most Americans. Despite the successes of the Apollo program and the current achievements of the shuttle program, only one in three Americans expresses a high level of interest in space activities. For those of us who are interested in space exploration, this level of interest may seem implausible, but it simply reflects the complexity of modern life.

For any given person the range of possible interests is vast. One of the characteristics of modern society is that the volume of information is overwhelming and no single individual can become or remain knowledgeable about more than a relatively narrow range of topics. In marked contrast to our frontier ancestors who waited eagerly for old newspapers from the East, the plight of the modern citizen is to sample selectively from the enormous volume of information available. Inevitably,

a specialization process emerges.

"Issue attentiveness" refers to a specialization process in which the following occur:

- individuals tend to focus their attention on a relatively small number of public affairs issues;
- they stay informed about only that set of issues; and
- any active citizenship role the individual may take is only in regard to those issues.

The concept of issue attentiveness was first described by Gabriel Almond in 1950 in discussing the public's understanding of and participation in foreign policy matters in the United States.[1] I have used the concept to study attitude development among young adults,[2] and to analyze adult participation in the formulation of science policy in the United States.[3] While the process of issue specialization is described in greater detail in other publications, it may be useful to review the basic rationale and impact of the process prior to using it as a means for understanding the basis of public attitudes toward space exploration.

The need for specialization springs from a combination of two basic forces. First, citizens in the latter part of the twentieth century are faced with a large number of competing demands for their time, of which they have only a fixed amount. There is ample evidence of the growth of time pressures over the last several decades and no evidence of a reversal of that trend.

Faced with a large number of competing and attractive demands on time, fewer adults decide to devote a significant share of it to public affairs. This has been observed, for example, in the steady decline in public participation in the political system over the last four decades. Even presidential elections, which command the highest levels of public concern and participation, attract barely half of the eligible adults in the United States.

Second, during the last forty years, the information threshold for many political issues has been increasing. An individual must now have more specialized information to be knowledgeable about almost any given public policy issue. Issues involving space exploration fall into this category, as do most of the areas of concern on the national political agenda.

The combined effect of these two forces has been the narrowing of the political horizons of most American adults to only a small number of public affairs issues. It is important to note that this is not the same process as "single issue" politics, which revolves totally around one strongly felt position; rather, it is a rational and gradual narrowing of the number of topics on which an individual can hope to remain adequately informed.

A Stratified Model

How, then, does this specialization process affect the formulation of public policy? In his original work, Almond outlined a pyramidal structure to illustrate the types of public participation in the policy formulation process that are likely to occur under conditions of issue specialization. In this stratified model, the policy makers are at the pinnacle of the system and represent those persons who have the power to make binding decisions on a given policy matter. This group would include a mix of executive, legislative, and judicial officers. In the case of space exploration, the officers would be primarily at the federal level.

The second level of the system consists of non-governmental policy leaders. In the case of space exploration, this group would include leading scientists and engineers active in aeronautics and astronautics, leaders of major corporations active in the area, disciplinary and professional societies relevant to space exploration, and, more recently, voluntary associations of interested and informed citizens like the Planetary Society and the National Space Institute. This leadership group interacts regularly with policy makers, and there is some movement of non-governmental policy leaders into

Three Studies of Public Attitudes

The analysis reported in this article is based on data from three national surveys. The 1979 national survey of adult attitudes toward science and technology was designed by Jon Miller and Kenneth Prewitt, conducted by the Institute for Survey Research at Temple University, and sponsored by the National Science Foundation (NSF contract C-SRS78-16839). This survey used personal, in-home interviews with 1,635 adults in a national probability sample.[1] The average interview took about 60 minutes, and included items about a wide range of scientific and technical issues.

The 1981 national survey was also designed by Jon Miller and Kenneth Prewitt, was conducted by the Public Opinion Laboratory at Northern Illinois University, and was sponsored by the NSF (grant #103662). This study utilized a national probability sample of households, a sample similar to that in the 1979 study, but employed telephone interviewing techniques. The interviews averaged 30 minutes and covered a wide range of scientific and technical issues and attitudes.

The 1985 survey of adult attitudes was designed by George Gerber, Nancy Signorelli, and Jon Miller. This survey was again conducted by telephone from the Public Opinion Laboratory at Northern Illinois University and was sponsored by the Annenberg School of Communications at the University of Pennsylvania. The interviews averaged about 25 minutes and focused on attitudes toward science and technology, attitudes toward scientists and engineers and the use of prime time television.

J.D.M.

NOTE

1. In a national probability sample, every person with a residence or an operative telephone (depending on whether the interview was conducted in person or by phone, respectively) has an equal chance of being picked for the survey.

Table 1
THE ATTENTIVE PUBLIC FOR SPACE EXPLORATION

	1979 (%)	1981 (%)	1983 (%)
Attentive public for space exploration	8.8	10.2	9.5
Interested in space exploration, but low in information	17.0	15.3	20.0
Interested in science, but not space	28.3	26.2	36.7
Not interested in space or science	46.0	48.2	33.7
N = Total number surveyed =	1,635	3,195	1,631

decision-making posts and of decision makers into the leadership group from time to time.

When there is a high level of concurrence between the decision makers and the leadership group, policy is generally made and there is no wider public participation in the policy process. On some issues, however, there may be a division of views among the policy leadership group itself, or between the policy leaders and the decision makers. In those circumstances, there may be appeals to the attentive public to join in the policy process and to seek to influence policy makers by direct contact and by persuasion.

The attentive public—the third level of the system—is composed of those individuals who are both interested in a given policy area and knowledgeable about that area. To be classified as attentive to a given policy area like space exploration, an individual must express both a high level of interest in space matters and the belief that he or she is reasonably well informed. The analysis that follows will look more closely at the size and composition of this attentive public for space exploration.

While the contacts and processes through which the leadership group mobilizes attentives in various policy areas are only now being studied, it would appear that there is a flow of appeals from leaders to attentives through professional organizations, specialized journals and magazines, and employment-related institutions. Attentives who contact public officials (policy makers) appear to use the traditional avenues of letter writing, telephone calls, and personal visits.

While attentiveness requires both interest and knowledge, another stratum of the public reports a high level of interest in space exploration, but assesses itself to be either moderately or poorly informed about the NASA program. This group will be referred to as the interested public for space exploration. In general terms, the subjectively perceived deficiency of knowledge about space exploration may be expected to make this group less likely to engage in direct contact with policy leaders or decision makers, but they are a pool of interested citizens that might be brought into the attentive category with an improved flow of information about space exploration.

At the bottom of the pyramid is the non-attentive public. For the most part, these individuals display a low level of interest in and knowledge about any given policy areas. However, it is important to understand two major points about this large group.

First, the general population always retains a political veto if they should become sufficiently unhappy about the policies that the decision makers, leaders, and attentives have fostered in any area. The role of the public in ending the wars in Korea and Vietnam illustrates the operation of this veto power. While the non-attentive public does hold political veto power, it rarely exercises it; this segment of the public on any particular issue has no active interest in that issue, and the time, energy, and effort necessary for organizing a successful opposition movement would require the members of this group to become attentive to that cause.

Second, it is important not to equate non-attentiveness to any specific policy area with ignorance or a lack of intellectual activity. We are all non-attentive to a vast number of areas and issues. Many of the persons not attentive to one specific issue area may be interested in and knowledgeable about numerous other issues.

In summary, the process of issue specialization has had a marked impact on the levels and forms of public participation in the formulation of public policy in specialized or technical areas. Unlike some previous theories of a technocratic elite that eliminate all public participation, this conceptualization recognizes that interested and informed citizens—especially in organized groups—can play a role in the formulation of public policy, especially when there are disagreements among the policy leaders or between the policy leadership group and the decision makers. It is not democracy in the tradition of the New England town hall, but if the model is correct it provides for significantly greater public intervention in the policy process than was thought possible only a few years ago. Additionally, it posits the possibility of a public veto on any issue that becomes sufficiently unpopular.

The Public for Space Exploration

How, then, do these ideas apply to the original inquiry about the level of public support for an expanded program of space exploration? If this model is correct, we should be able to define and identify an attentive public for space exploration and to examine its composition and its policy at-

titudes toward the space program.

Utilizing data from a series of national surveys conducted in 1979, 1981, and 1983 (see box on page 27), one can infer that approximately one in ten Americans has both a high level of interest in space exploration and believes himself or herself to be informed about space matters (see Table 1). The size of this attentive public for space exploration has been relatively stable over the last six years, suggesting that peaks of interest in the shuttle and similar activities do not have a substantial impact on this core group. In the context of the earlier discussion about the process of issue specialization, this should not be a surprising result.

The same data suggest that the size of the interested public for space exploration has increased slightly in recent years. The effect of the shuttle program may be reflected in a higher level of interest about space among this segment of the public, but, by their own report, this group does not feel that they understand or know very much about the space program. The 20 percent of the American people in this segment translates into 34 million adults. It would seem apparent that one of the high priorities of the public information program of both NASA and non-governmental groups interested in space should be the focusing of informational activities on this group.

By the logic of the stratified pyramid model, the remaining 70 percent of the American people are not attentive to space exploration—that is, they have little interest in or knowledge about the space program. Because of this lack of interest, and given what we know about the communication of scientific information to the public, it would appear to be very difficult to reach this segment of the population.

Using the same logic, data sets, and methods as applied to space, it is possible to identify that segment of the public that has a high level of interest in scientific and technological matters other than space. While many persons who are interested in science and technology in a broad sense are also attentive to or at least interested in space, the data from the three surveys indicate that about 37 percent of the adult population—about one-half of the uninterested segment—expresses a high level of interest in science or technology, but not in space. A full discussion of the implications of this pattern of interests is beyond the scope of this article, but it is worth noting that this segment of the public might be expected to become more interested in space matters if the activities of the space program were viewed as more scientific in character.

In short, there is a solid core of about 10 percent of the American people—about 17 million citizens—who are attentive to space exploration. This is the segment of the population that we would expect to hold the most positive views of the space program and to be the most willing to engage in direct political activities to further space exploration. An additional 34 million Americans have a high level of interest in the space program but think that they do not have an adequate understanding

Table 2
ATTITUDES TOWARD THE SPACE PROGRAM

N (1981) =	327	490	838	1,540
N (1983) =	155	327	599	550

of the program. Almost 50 million more citizens reported a high level of interest in science and technology issues, but not in the space program itself. It would seem that the space program enjoys both a viable core attentive group and has the potential of substantially expanding this group with improved information programs.

Who Is the Attentive Public?

In broad strokes, the attentive public for space exploration is generally under 45 years of age, relatively better educated than most American adults, and twice as likely to be male as female. Approximately 40 percent of the attentive public for space exploration holds at least a baccalaureate. Almost half of the attentive public reported having completed one or more college-level science courses, and 33 percent indicated that they have completed four or more college science courses. Most of the attentives were in upper elementary or high school at the time of Sputnik and experienced the first years of the space race as adolescents or young adults.

In contrast, those citizens categorized as the interested public for space exploration tend to be slightly older and slightly less well educated. Only 30 percent of this group has earned a college degree. Women make up 54 percent of the interested public for space exploration.

At the other end of the spectrum, those persons reporting low levels of interest in space and in science tend to be older, significantly less well educated, and much less likely to have completed a college-level science course. Approximately three out of five persons in this segment of the public are women.

Attentive Public's Policy Views

Having identified a segment of the public that has a high level of interest in space exploration and believes itself to be adequately informed on the issues, it is appropriate to ask, "What are the policy preferences of this attentive public?" If this group were to hold essentially the same views of the space program as the rest of the adult population, there would be little rationale for a special political role for this group.

Data from the same three surveys discussed earlier indicate that the attentive public for space exploration holds significantly more positive views of space exploration than any other segment of the American people. On the basic commitment to continue the space program, for example, the attentive public is virtually unanimous in its support of space exploration, while only half of the uninterested public would favor continuing the program (see Table 2). Similarly, over 70 percent of the attentive public expressed the view in 1981 that the benefits of the space program exceeded its costs.

The attentive and interested publics are markedly more optimistic about the future achievements of the space program than other segments of the public. On a wide range of other nonspace items discussed in the surveys, the attentive public was generally more optimistic about technological achievements than were other segments of the public.

On the critical issue of funding, the commitment of the attentive public to space exploration is most apparent. Half of the attentive public expressed the view in 1983 that space spending is currently too low and only 7 percent of the attentives thought it too high (Table 2). In sharp contrast, only one-third of the interested public thought current spending was too low and only 9 percent of the nonattentive public shared that view. If dollars are the necessary fuel for space exploration, then the attentive public is prepared to support the continuation and expansion of current federal funding for space.

The 1981 survey posed a situation in which limited resources precluded pursuing all objectives of the space program with equal vigor. Each respondent was asked to indicate whether he would prefer to see primary emphasis placed on either deep space probes or orbital service systems. The results, as shown in Table 2, indicated that about two-thirds of the attentive, interested, and residual science-oriented publics favored placing primary emphasis on orbital service systems under such conditions.

The 1979 survey asked each respondent to cite the benefits of space exploration. He or she could mention up to two benefits, and the following analysis includes both of those responses. The data indicated that the attentive public is most likely to see technological spin-offs and the discovery of new minerals and materials as major benefits (see Table 3). The interested public is the second most likely group to recognize these benefits.

With regard to basic knowledge about the universe, a third of the attentive public cited this benefit from space exploration, as did 22 percent of the interested public. Only 9 percent of the residual science-oriented public cited this result as a major benefit, despite their apparent high level of interest in science or technology.

It is clear from these data that the members of the attentive public are far better informed about the current and potential benefits of space exploration than are the other segments of the population. It should be noted, however, that the majority of both the residual science-oriented public and the non-attentive public could not name a single benefit of space exploration.

The 1979 survey also asked each respondent to cite up to two potential harms that might result from space exploration. The following analysis includes both of those responses.

The data indicated that the attentive public for space exploration was also more aware of potential hazards than were the other segments of the public (see Table 4). The major concern of the attentive public was the

transmission of new diseases from space to the planet Earth, undoubtedly reflecting in large part the impact of Michael Crichton's *The Andromeda Strain*.[4] The attentive public was also sensitive to potential dangers to the astronauts themselves, to weather modifications, and to the cost of the program.

The interested, residual science-oriented, and non-attentive publics were able to name relatively few specific potential harms from space exploration. This result indicates that negative feelings toward the space program are rarely based on substantive information, suggesting that for those segments of the public other than the attentive public these views may be classified as "opinions" that are neither deeply rooted nor strongly held.

Can Attentives Have An Impact?

The major remaining question is whether the attentive public for space exploration can make a political difference with regard to either the NASA program objectives or to the level of funding. To deal with this question, it will be necessary to compare the political activities of the attentive public for space exploration with the other segments of the public. If the attentive public demonstrates a differential pattern of political behavior, it will then be necessary to fit those behaviors into the policy formulation processes characteristic of such non-electoral issues as space exploration.

Political Participation

Data from the 1979, 1981, and 1983 surveys indicate that the attentive public for space exploration is only slightly more active in direct electoral participation than other segments of the public, but that attentives are significantly more active in non-electoral participation—what James Rosenau calls "citizenship between elections."[5] Approximately three out of four citizens reported voting in at least one election—local,

38-036 O - 84 - 16

state, or national—in the last four years, and the attentive public was not significantly more active in this regard than other segments of the public (see Table 5). The attentive public was, however, significantly more likely to have made a political contribution to a candidate or party than were other segments of the population, suggesting that its members are indeed aware of the efficacy of political money and of the value of being remembered for their support.

In terms of overt partisanship, the data from the 1981 study indicated that the attentive public comprises almost equal numbers of Republicans and Democrats. About one in five attentives considered themself to be independent. This distribution of political loyalty provides a valuable bipartisan character for the activities of the attentive public for space exploration.

The most important facet of the political participation of the attentive public for space is the recognition of the importance of direct contact with decision makers in the formulation of public policy and the willingness to engage in that contacting process. Over one-third of the attentive public reported that they had contacted a public official on a policy matter, and 25 percent claimed that the contact involved a science-related policy matter (Table 5). When asked about the likely efficacy of contacting a public official, the attentive public was more optimistic that a personal contact would produce a desired policy outcome than were other segments of the public.

To better understand the stimuli to participation, the 1979 survey included a hypothetical policy dispute over the issue of seeking to communicate with other civilizations. Each respondent was told:

Let's suppose that one group of scientists wants to send radio messages into deep space to try to communicate with other civilizations, but another group of scientists believes that this could lead to conquest of our civilization by more advanced groups that might receive the signal. In a case of a conflict like this, which one of the groups listed on this card do you think would be the best qualified to decide the issue?

The data from the 1979 survey indicate that half of the attentive public would have relied on the advice of scientists and engineers who specialized in the area (see Table 6). The United Nations was cited second most frequently by the attentive public, with 17 percent indicating a preference for a UN decision. About 15 percent of the attentive public preferred to have the decision made by the administrators of NASA, and a similar percentage indicated a preference for a decision by citizens in a national referendum. While all four segments of the public deferred to the opinions of scientists and engineers who specialized in the area, NASA was the second most frequent choice for the three segments other than the attentive public.

The importance of the selection of scientists and engineers by the attentive public is that it is likely that the spokesmen for the major points of view on the issue would have come from the science and technology policy leadership group. The stratified model predicted that the attentive public would turn to this group, and the prediction was confirmed. The finding that all four segments of the public made the same choice indicates that reliance on ex-

pertise is deeply rooted in American society.

The 1979 survey used the same hypothetical policy dispute to ascertain the likelihood of personal participation in the dispute by the attentive public and the other segments of the public. Each respondent was asked to indicate the likelihood that he or she would personally take some role in the dispute, and the resulting data indicated that 66 percent of the attentive public would have participated in the dispute (see Table 5). In contrast, only 3 percent of the non-attentive public indicated that they would definitely participate, and an additional 17 percent thought that they might take some part in the dispute. The interested public reported the second highest rate of expected participation.

Priorities for Federal Spending

The most concrete and important point of public participation in the policy formulation process concerning space exploration is the federal budget process. With the adoption of revised budget approval procedures in Congress that require agreement on a government-wide expenditure ceiling, the process has become a zero-sum game: every interest must now compete against all other interests for a share of the available resources. It is at this point that the impact of attentiveness can be seen most clearly.

To allow an examination of public spending priorities for the federal government, the 1981 survey included a question that presented a series of programmatic objectives and asked each respondent to judge whether the government was spending too much, too little, or about the right amount on each area. On the question of space exploration, 57 percent of the attentive public for that issue reported that the federal government was currently spending too little on space exploration, and only 13 percent of the attentive public expressed the view that federal support for space was too high (see Table 7).

In sharp contrast, a majority of the non-attentive public indicated that the federal government was spending too much on the space program. On no other issue was the division between the attentive public (together with the interested public) and the non-attentive public so sharp.

As noted previously, the attentive public for space exploration is not a "single-issue" group. While 57 percent of the attentive public thought that the federal government was spending too little on space, a majority of the same attentive public expressed the view that the federal government was also spending too little on assistance to older persons, education, health care, and scientific research. Since a majority of all four segments of the population thought that the federal government was spending too little on assistance to older persons, health care, and education, the attentive public was a part of a broader national consensus on those issues.

On the question of spending for national defense, the attentive public for space exploration was badly split. Slightly over one-third of the attentive public expressed the view that the federal government was spending too little for national defense, while another third of the attentive public voiced the view that the federal government was spending too much for national defense. Only 29 percent of the attentives thought that the spending level was about right.

While these data set a context for federal spending that covers most of the major programmatic objectives of the federal government, the 1981 survey also posed the hypothetical circumstance of a stable level of federal resources for scientific research and development and asked each respondent to indicate whether

he would increase, decrease, or hold constant the share of research and development funding for a series of programmatic areas within science and technology. Given those conditions, 69 percent of the attentive public indicated that they would favor an increased share of scientific research and development funds for space exploration, and only 7 percent supported a smaller share for space exploration (see Table 8). The interested public displayed essentially the same distribution of attitudes on the reallocation within science and technology question. The modal choice within the residual science-oriented public was to hold constant the share for space exploration.

Again, the attentive public for space exploration demonstrated a breadth of interest that went beyond the space program. A majority of the attentive public for space exploration also favored an increased share of scientific funding for disease-specific medical research, research on human learning, basic physics research, and basic chemistry research.

Support for Space Exploration?

What, then, does all of this mean for the formulation of public policy in regard to space exploration? In the first place, it should now be clear that the original question is too global and not reflective of the policy formulation process. Space exploration is not a topic of high interest to the majority of American adults and is seldom an electoral issue. Rather, public policies toward space exploration are hammered out in traditional legislative and executive branch processes.

In this context, the active participation of the attentive public for space exploration in making direct contact with decision makers indicates both an understanding of the process and a willingness to play the game. The greater propensity of attentives to make political contributions to electoral candidates denotes the same kind of political savvy.

At this point, it is important to note that the attentive public infrequently initiates a wave of contacting behavior without some encouragement from the policy leadership group. Most of the people in the attentive public are busy with work and other daily goals, and the urge to write a congressman or to make contact with a public offical rarely surfaces without some stimulation from either the news media or a policy leader or group. In contrast, for example, a mailing from Carl Sagan on deep space probes or from the National Space Institute on funding for the shuttle program may mobilize an individual to make a direct contact on an issue. In general terms, I would argue that the policy leadership groups associated with space exploration are only learning how to play the game effectively and that their future political impact will be far greater than their past efforts.

What the data show is that there is a viable core group of approximately 17 million Americans who have a high level of interest in space exploration, who perceive themselves to be functionally literate in the area, and who hold very positive policy attitudes toward the space program. Further, the attentive public for space exploration appears to have an

understanding of the rules of the game for the practice of politics between elections and some track record of making personal contacts with decision makers. The potential for the mobilization of this group is far greater than its previous utilization.

Intuitively, many people feel uneasy about a core group of only 10 percent. Is this enough? Should the policy leadership groups be actively seeking to expand it? The answer is not simple, but it is worth noting that the attentive public for space exploration is about the same size as the attentive public for foreign policy (there is some overlap, of course) and larger than the attentive public for agricultural policy. On the other hand, it is only half as large as the attentive public for broader science and technology issues and about one-third of the size of the attentive public for economic policy.

On balance, I would say that the current attentive public is large enough to be effective in the policy-making processes when effectively mobilized by the leadership groups. At the same time, it never hurts to have a somewhat larger group. The data outlined previously suggest that there are at least 34 million additional citizens who have a high level of interest in space exploration but who do not feel adequately informed about the area. An aggressive, long-term program to identify and communicate with this group would almost surely increase the size of the attentive public for space exploration.

Further, there are additional millions of citizens who are very interested in science in general but who do not find space exploration to be a topic of interest. To the extent that this group can be persuaded of the importance of the scientific mission of the space program, some of those individuals might be expected to develop a continuing interest and knowledge base about space matters.

Looking at the question of public support for space exploration in the broader context of the political process, it would appear that there is a strong core segment of the public committed to the support and advancement of space exploration. In the absence of an organized opposition to space exploration, the attentive public for space is likely to exercise considerable influence. To effectively employ this group, however, it will be necessary for the policy leadership group to better understand the non-electoral policy-making process and to more consciously address the identification and cultivation of the attentive public for space exploration.

Why NASA's space shots don't reach for the stars.

MISSION OUT OF CONTROL

BY TINA ROSENBERG

WHILE Neil Armstrong was taking his giant step for mankind on the Moon in 1969, the National Aeronautics and Space Administration was soaring back on Earth. By meeting President Kennedy's 1961 challenge to land a man on the Moon within the decade, NASA had proven communism was no match for American know-how and the American way of life. A decade of race riots, assassinations and war culminated with the stars and stripes planted in the Sea of Tranquility.

But following the Moon landing, NASA went through a postpartum depression on a grand scale. Employment in the space program, once 420,000, declined to 160,000 by 1971. Laboratories closed. NASA's budget, once nearly $6 billion, dropped to slightly more than half that amount. After enjoying high status, the excitement of working on a top-priority challenge, and all the money it needed, NASA was faced with the question: Now what?

The agency responded by asking for the moon. In 1970 and 1971 NASA requested money for a reusable space shuttle to carry cargo to space cheaply, and for a 100-man orbiting space station by 1980, and for a $24 billion manned mission to Mars, and for a commitment to a lunar base. To fill in what it thought would be a gap in manned space flight between the last Apollo mission and the start of the shuttle, NASA even proposed a mini-shuttle, which it admitted had limited use.

In short, NASA had gotten hooked on the size and glamour of manned programs. It's easy to see why. NASA was—and still is—convinced that only manned missions can focus public interest in space and persuade Congress to fund NASA's programs. "Supporting astronomy is like supporting ballet," says Alexander Dessler, director of the Marshall Space Flight Center in Huntsville, Alabama. "There's no clear, immediate benefit." But by showing Americans performing dangerous missions in space, NASA captured public attention with a human drama. NASA has always understood the P.R. value of human derring-do. When choosing astronauts for its first manned program, Mercury, NASA tried to find candidates who fit the public's conception of clean-living All-Americans who could represent the United States in its race with the Russians. Once the astronauts were chosen, *Life* magazine airbrushed their lives, and NASA changed their role from passenger to the more heroic job of pilot. Astronauts can also make speeches and testify before Congress—a skill no satellite will ever master.

But public attention is not the only advantage NASA gets from manned programs. "It's difficult to know where the public interest in seeing man in space stops, and NASA's inclination to keep people employed starts," says a Senate staffer. No. 1 on NASA's current list of eight goals is "maintain the institution."

If NASA wants to keep its scientists and engineers busy, the best way is through manned programs. Manned spacecraft are larger, more expensive, and more time-consuming to build than unmanned vehicles because they require food, water, oxygen, and back-up systems that are not needed for unmanned vehicles. Manned vehicles need to bring astronauts safely back to Earth, which necessitates more tests, longer trips, and re-entry hardware such as heat shields. Most important, a manned program, unlike a scientific program, usually implies a commitment to multiple launches and ambitious space goals.

NASA not only worries about employing its own personnel, it also looks out for the aerospace industry. As with the Pentagon, the line between government and industry blurs when the two work together on twenty-year projects. "We work so closely together that we jokingly call ourselves 'partners-in-crime,' " says Peter Eaton of NASA's Expendable Launch Vehicle office, speaking of NASA and the McDonnell Douglas Corporation, which makes the Delta rocket. It is commonplace for NASA to recruit industry engineers and for NASA officials to leave the agency to work for a contractor.

Although NASA had asked in the early 1970s for funds for just about every manned project imaginable, Congress and President Nixon did not comply. With his budget stretched by the Vietnam War, Nixon approved only the project NASA touted as a money-saver: the space shuttle. The shuttle, it was claimed, was a kind of cheap, efficient truck that would haul materials and satellites into orbit. It would be less expensive than expendable rockets because while it would need a new fuel tank and refurbished booster rockets for each mission, the airplane-shaped orbiter would be reusable. At a development cost set for $5 billion and a much lower operating cost than disposable rockets, the shuttle would lower the cost of

p. 18 - 21

commuting to space and therefore of all future space missions.

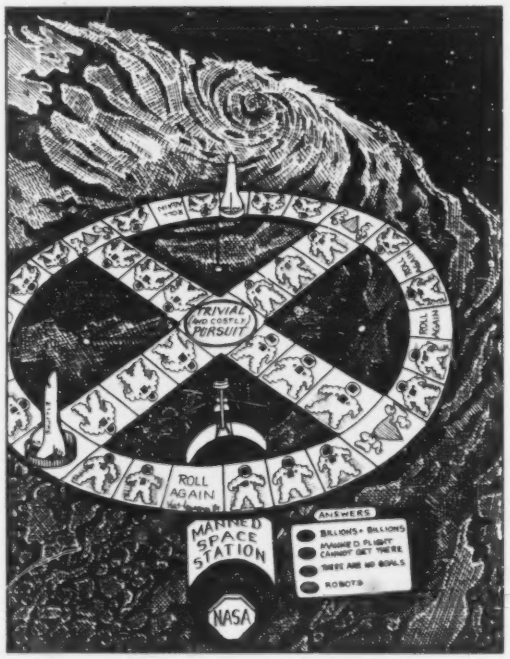
From the beginning the shuttle proved balky. Scheduled to launch in 1977, it didn't make its first test until April 1981 and wasn't operational until November 1982. By the time the shuttle was open for business, development costs had ballooned from $5 billion to $15.5 billion. NASA is still ironing out minor problems, but the shuttle's real flaw won't go away: it's no cheaper to operate than NASA's old Chevy, the Delta rocket.

At first glance, the shuttle does look cheaper than launching the same payload with the Delta. Let's say your commercial firm wants to launch four communications satellites in 1986 into geostationary orbit (G.S.O.) 22,000 miles above the equator. At G.S.O. a satellite rotates with the Earth—a satellite placed over Quito, Ecuador, stays over Quito, Ecuador. With the Delta, each launch will cost $25 million. Total price for launching four satellites: $100 million.

The shuttle can carry four times the Delta payload, but it requires a two-stage trip because it orbits a mere 350 miles up, practically skimming the Earth's surface. To kick your satellite up to G.S.O., you need a Payload Assist Module, or PAM. (The PAM is the part that malfunctioned two flights ago and flung two satellites into the wrong orbit in the process.) Each PAM will cost $4 to $5 million, for a cost of about $18 million for four. From 1986 through 1988, you can book the whole shuttle—enough for your four satellites—for $79.4 million. So for your 1986 shuttle mission to G.S.O., you will pay a total of $97.4 million. You save all of $2.6 million over the cost of Delta rockets.

But what's important to recognize about the shuttle is that price to customers has no relation to the actual cost of the shuttle. "For realistic missions during the next twenty years or so, the shuttle system is actually more expensive than are conventional, expendable boosters," Dr. James A. Van Allen, professor of astronomy at the University of Iowa wrote in 1982. The shuttle looks cheaper because NASA subsidizes its missions.

It wasn't meant to be that way. Shuttle prices were set in 1972, when NASA predicted there would be 572 flights. The problem is that the shuttle won't fly 572 missions; NASA now estimates only 234 missions before the machine is ready for the Smithsonian. That gives NASA fewer flights over which to amortize the cost of building the shuttles and a shorter time in which to learn to operate more efficiently. As a result, costs have soared—this year, each shuttle launch costs $200 million. NASA had planned to raise the price of post-1988 missions to recoup the money it is losing now but NASA has changed its mind. NASA senior staff engineer Barbara Stone says that by 1988, the shuttle will still cost over $100 million per flight—too much for NASA to charge and stay competitive. "I don't think we'll recover those cost underruns," Stone says.



DRAWING BY VINT LAWRENCE FOR THE NEW REPUBLIC

NASA claims the shuttle can save money another way, by repairing and redeploying ailing satellites. In April, shuttle astronauts repaired the Solar Maximum observatory. But the shuttle can only reach satellites in or near low Earth orbit, which is where Solar Max was stationed. The vast majority of satellites are in G.S.O., a good 21,650 miles beyond the shuttle's reach. And what NASA does not mention is that there was no reason to build the shuttle to host satellite repair missions. Expendable rockets can do the same job, and they can travel to G.S.O. According to Arthur Koski, spokesman for the Martin-Marietta Corporation, which worked with NASA to repair Solar Max, the only reason rockets can't do repair missions is that we don't have any. "Our only manned spacecraft is the shuttle," says Koski. "And at this point it wouldn't make much sense to build rockets."

NASA's last commercial Delta launch is scheduled for the end of this year. By getting rid of the Delta program NASA will no longer steal business from itself. But the

shuttle still faces competition from emerging for-profit rocket companies. NASA is putting the finishing touches on an agreement with a private company, Transpace Carriers Inc., to take over existing contracts for the Delta. The company plans to make its first launch in 1985 or 1986. NASA already has competition from the European Space Agency's Ariane rocket. Arianespace has one model, the Ariane 3, that can throw half the shuttle payload (or two Delta payloads) into G.S.O. for $25 million, including the boosters. Total cost of a shuttle-sized payload: $50 million. And because Ariane is out to make money, that is not a subsidized price. Western Union, GTE, and INTELSAT among others have launched satellites on Ariane.

Why can Ariane deliver at half the shuttle's price? "We're not a man-rated vehicle," explains Jean Michel Eid, assistant manager of Arianespace in America. It's people and the life support and safety systems they require that keep the shuttle from lowering the cost of space travel.

Now that the shuttle is working, NASA is at another critical point: the decision of what to do next. Keeping in mind the advantages NASA reaps from manned programs, agency administrator James M. Beggs chose the space station. When he first asked for funds he ran into a wall. The Space Science Board of the National Academy of Sciences said a space station had no scientific purpose. The Pentagon said it had no military purpose. David Stockman, director of the Office of Management and Budget, thought it was too expensive, and the science adviser to the President, George Keyworth, thought it was too boring to generate the kind of excitement the Apollo mission had created. Fortunately for NASA, Beggs found a believer in President Reagan, who endorsed a permanently manned space station in his State of the Union Address and put seed money for it in his 1985 budget.

BEGGS CONVINCED Reagan of what has become NASA's guiding vision: a modern version of manifest destiny that sees Americans living and working in space. This philosophy is almost devoid of any idea about what we will do there. Being there, apparently, is enough. At a November 1983 Congressional hearing, T. F. Rogers of the Office of Technology Assessment testified, "To our knowledge, there is no comprehensive and thoughtful list of goals." On NASA's twenty-fifth anniversary in the fall of 1983, Beggs wrote, "I believe that a space station, is, indeed, an idea whose time has come. Sooner or later, this country is going to take the next logical step in space and will build one. And the sooner we do so, the better it will be for us, because a space station is essential if we are to maintain our preeminence. I see a space station as an essential stepping-stone to the future."

NASA has what seems to be an enlightened attitude toward space: a place where poets and painters as well as scientists can work. "I'm not prejudiced," says Hans Mark, deputy administrator of NASA. "I see a future where people doing things not associated with space will go there. It is the obligation of any great civilization to support the arts."

If you happen to be the poet or pioneer chosen to live in space, this idea is exciting and romantic. If you're the taxpayer signing the lease for this high-rent suburb, however, its appeal pales somewhat. Cost is something space visionaries never seem to think about. Never mind that settling the Sahara would cost far less than housing a large number of people in orbit. Never mind that you could keep thousands of artists from starving on Earth for the price of putting one a little bit closer to the stars. The idea of a space colony allows NASA to view manned missions as their own justification, at the expense of commerce, science, and exploration.

SPACE travel has never quite lived up to its billing as a technological bonanza. The science and engineering feats it encourages have only limited use here on Earth. Trickle-down technology is not an efficent way to regain our competitive economic edge. And the spin-offs space has given us such as hand-held calculators, digital watches, phone calls via satellite, improved computers—just about everything except Tang—have come from programs that have one thing in common: they were unmanned. "There's an inverse relationship between the payoff of a mission and the importance of man," says Wallace A. Berger, staff director of the Senate subcommittee that oversees NASA. "An overemphasis on manned missions forecloses advancing science or producing something of commercial value."

This is because building new ways to carry men in space offers little of value to earthlings. The shuttle's efficient engines that burn super-cold hydrogen and oxygen, for example, have no other use except in the dubious cause of the MX missile. In contrast, unmanned planetary probes have spawned new ways to send information and pictures over very long distances, the basis for new communications technologies. Moreover, designing missions for men creates less technological innovation than creating an automated mission to do the same tasks. If an astronaut is around to change the film in an observatory camera, there is no reason to develop the robotics to do it automatically.

Recently, speculation about the commercial benefits of space has centered on taking advantage of space's zero gravity and near-perfect vacuum to process new metal alloys and pure chemicals. NASA sees the space station as a space factory. But just as with the shuttle, the manned space station faces competition from cheaper, easier to build, unmanned space manufacturing platforms. The key to economically viable space manufacturing is doing the job more cheaply than on Earth. That means robotics. While manned work might be prohibitively expensive, an automated mission at one-twentieth the cost could make space processing profitable. The Fairchild Corporation is developing an unmanned space platform

called Leasecraft which it hopes to launch in 1987—about seven years before NASA's space station is supposed to be ready.

One of the first tests of Leasecraft's commercial potential will be electrophoresis, a gravity-free way to make pure pharmaceuticals, developed jointly by Johnson & Johnson and McDonnell Douglas. Electrophoresis is the best-developed space manufacturing process, and manned space station supporters invariably mention it as a project that they could put in orbit. But far from needing a manned space station, electrophoresis is fully automated, needing only periodic human tending—and there is a good chance its manufacturers will sign with Leasecraft. (It's no surprise that NASA is now exploring the idea of launching an unmanned space platform.)

INSTEAD OF encouraging cost-effective automatic work, the space station will subsidize an inefficient method of processing. "It's like buying an expensive car, pretending it didn't cost you anything, and comparing it to the cost of taking a taxi," says Richard Garwin, former science adviser to President Carter. "When you offer free passage, people will take you up on it." And just as with the shuttle, if NASA stops subsidizing industry and charges prices that reflect the space station's true costs, it will lose the price war with unmanned platforms.

More harmful than the manned program's effect on commercial industries is its impact on space science. The space station just won't support an adequate scientific laboratory. The first problem is that the space station must stay in low Earth orbit, too low for many experiments. For example, the space station can't do experiments on the solar wind (vast currents of ions that affect the weather and telecommunications) because it can't reach the solar wind. But more crippling, it is manned. "All experiments and observations can be done equally well or better by instruments than by men," says Dr. Thomas Gold, a Cornell University physicist. "For observations, the presence of a man is a disaster. He can't keep still enough." The advantage of having a telescope where no atmosphere distorts light is lost if there are humans tromping around literally rocking the boat.

There are, of course, experiments you need men for: experiments on men. But that's about all. Communications and robotics have become sophisticated enough so that experiments can be tended by remote control from Earth about as well as by men in a capsule. Ask scientists what kind of missions they would choose to do their experiments, and they will say small, unmanned (and cheaper) go-anywhere capsules built to the specifications of particular experiments.

The debilitating impact of the shuttle and the space station is even greater where exploration is concerned. Because of the moon shot, the public has come to confuse "exploration" with "manned exploration," a mistake NASA does little to correct. In fact, *unmanned* exploration is the best way to expand our space horizons. Take one of NASA's most ambitious goals, a manned expedition to Mars. Thanks to the Viking Mars lander we have charted Mars' weather, atmosphere, soil, and volcanoes. For almost any space mission, unmanned probes with cameras and scientific equipment can find as much about a new surface or atmosphere as a man can learn. It's not the next best thing to being there—it is being there. "Instead of seeing the surface directly, you'd see it through a TV camera," says NASA's Dessler. There are only two differences between manned and mechanical exploration. One is that manned missions cost twenty to thirty times more than unmanned missions; Sally Ride on Mars would be nothing more than a $100 billion flag-planter. The other is that to most places we want to go, such as Venus or Jupiter, we can send instruments—and we can't send men.

The most lofty justification for manned space travel is that it satisfies, as all "Star Trek" fans know, the urge "to boldly go where no man has gone before." But a mission to Mars would be timidly revisiting a place we went years ago. As an expression of the human spirit, manned space exploration is rather complacent. Preferring a lunar base to real exploration is like Columbus saying to Queen Isabella, "I'll pass on the ships but why don't you give me some money to take a Mediterranean cruise?"

Even if we do want to prepare for future manned missions, the space station is the wrong first step. We already know how to acclimate humans to space life, and we know how to build rockets in space. Our challenge is to find a sufficiently powerful propulsion method to travel throughout the solar system. A space station can only launch deep space travel after that problem is solved.

THE REAL *Niñas* and *Pintas* today are unmanned observatories and planetary probes. And the cost overruns of the shuttle drained money from their important missions; the space station is threatening to do the same. Because of the shuttle, the United States is not launching a probe to sail through the tail of Halley's comet in 1986 and gather samples, as the Soviets and Europeans are doing. NASA canceled the Mars Rover, which would have scooted around Mars' surface and brought back samples from many sites. It canceled the Grand Tour, a satellite mission that would have taken advantage of an alignment of all the outer planets that won't occur again at least until the year 2110. It canceled the Mariner mission to study the mysteries of Jupiter's atmosphere and to give us a first glimpse at the moons of Uranus. The United States has withdrawn our satellite from the International Solar Polar Mission leaving just one European probe to fly past regions of the sun which we have never seen before. NASA has also abandoned the Sun Blazer, a proposed craft that would have flown within 4 million miles of the sun's surface.

Ten years and $20 billion from now, when the space station is operating, what can we expect? Almost certainly, NASA will ask for that manned Mars mission or lunar base, invoking words like "American preeminence" and "fulfilling our destiny." But what NASA will not talk about is how little its projects will capture the wonder and romance of true space exploration.

SPACE SCIENCE RESEARCH IN THE UNITED STATES

A TECHNICAL MEMORANDUM

SEPTEMBER 1982

Technical Memoranda are issued by OTA on specific subjects analyzed in recent OTA reports or on projects presently in process at OTA. They are issued at the request of Members of Congress who are engaged in committee legislative actions which are expected to be resolved before OTA completes its assessment.

Reproduced from U.S. Congress. Office of Technology Assessment. Space Science Research in the United States: a technical memorandum. [Washington, For sale by the Supt. of Docs., G.P.O., 1982] 50 p.

CONGRESS OF THE UNITED STATES
Office of Technology Assessment
Washington, D.C. 20510

Preface

Selective budget cuts and reallocation of funds within the National Aeronautics and Space Administration's space science program have left planetary science, solar and heliospheric physics, gamma ray astronomy, and X-ray astronomy with uncertain futures. Indeed, many in the space science community think that the program has lost its sense of direction and that it is time for national goals for space science to be articulated. Responding to this concern, Rep. Cooper Evans of Iowa requested the Office of Technology Assessment (OTA) to examine the direction and purpose of the U.S. space science program. In particular, Rep. Evans asked OTA to "assist Congress in evaluating the effectiveness of our space science program and in discovering what its future needs are."

In undertaking the study, OTA sought the contributions of a wide spectrum of knowledgeable and interested parties. To this end, a questionnaire, designed to elucidate the issues and problems in the current conduct of the U.S. space research program, was sent to representatives of several Federal agencies, space scientists, and staff members of congressional committees and individual Congressmen. Over 80 formal replies were received. Concurrently, OTA arranged a number of separate meetings and discussions with these three groups for additional detailed evaluation of the issues. These various contributions were then organized into background reports which served as the basis of a workshop held at OTA on May 5, 1982.

The following technical memorandum summarizes and critiques the views of many people interested in space science, several of whom attended the workshop. In preparing this document, OTA did not attempt to obtain the views of those who are opposed to or uninterested in space science, nor did OTA attempt to rank space science against other national priorities.

Chapter 1

Summary

The information presented in this document derives primarily from consultation with a wide spectrum of people involved in space science. In undertaking this study, OTA did not obtain the views of those outside the space science community, nor did OTA attempt to rank space science against other national priorities.

CURRENT SITUATION—DESCRIPTIVE

Despite its many noteworthy achievements over the past 20 years, the space science program of the United States has, as a whole, been placed in a holding pattern and, in significant parts, been forced to retrench. Many now see space science as in a state of crisis. The National Aeronautics and Space Administration's (NASA's) overall budget for space science has, in general, been on the decline since 1974 (see app. C), and that of one category, planetary science, has declined precipitously. For the latter part of this period, the space science budget for physics and astronomy has been on the rise, but this increase is largely being spent on a single major project, the Space Telescope.

As a result, few missions are in prospect: in planetary science, only the major Galileo mission to Jupiter is planned for the 1980's; in solar and heliospheric physics and X-ray and gamma ray astronomy, all major missions have been postponed. Not only have the numbers of missions decreased, but there is insufficient funding for important interim activities such as data analysis. Thus, there is an uncertain future, not only for planetary science, but also for several subdisciplines which fall under the rubric of physics and astronomy.

Two additional factors make the situation particularly acute. First, most research activities follow a cycle in which new subdisciplines are born, grow to maturity, and then taper off into a continued, but reduced level of activity. But space science, as a relatively new field of research, finds itself with all of its subdisciplines still ripe for further growth. No space science subdisciplines have yet reached a point of naturally reduced activity. Given this situation, the general truth that, with a relatively constant level of overall funding, growth of some subdisciplines can occur only at the expense of others, becomes of particular concern. Second, as the number of missions has declined, those that remain have tended to be more complex, sophisticated, and expensive, and have tended to squeeze out the smaller and less expensive missions which have in the past supported a broad research base. These two factors, taken together, make it difficult for a number of productive teams of researchers in universities and in industry to remain viable.

CURRENT SITUATION—ANALYTIC

In all U.S. pronouncements on space policy, from the 1958 National Aeronautics and Space Act to the White House Fact Sheet on National Space Policy, released on July 4, 1982, continuing progress in space science is cited as a national goal. Because of this general policy, space science receives some portion of the Federal budget for space activities. Unlike the manned program, however, space science has never been directed toward a particular goal of unequivocal priority. Without the kind of commitment that arises from acceptance of a challenge to meet a particular goal, space science research has been conducted in a mode where the programs undertaken are determined primarily by whatever budget is made available (the levels of which fluctuate wide-

98-706 O - 82 - 2

ly) and only secondarily by scientific goals. Furthermore, even within the budget made available for all of space science, the importance of certain scientifically critical activities has not always been recognized. As a result, no base budget has ever been set to ensure that these activities are sustained.

The impacts on space science from the manned program are often substantial. Large development programs, like Apollo or the Space Transportation System (space shuttle), are undertaken as national political commitments, and therefore have the highest priority within NASA. When these programs experience cost overruns, they tend to draw funds away from NASA's other programs, including that of space science. When there is pressure to move funds out of space science into other parts of NASA, the purely scientific activities—data analysis, theory, and mission design—are the least protected.

An analogous problem exists *within* the space science program in that large science projects, like Viking or Voyager, tend to draw funds away from the smaller ones. A significant measure of the past success of NASA's space science program has resulted from a balance of large and small projects undertaken at the same time; a certain concern, therefore, must attend the possibility that, with limited total funding, the few remaining projects may be large, leaving no support for small ones. There is an additional concern that, especially with approval of new-start status for small missions at least as difficult to achieve as for large ones, missions originally designed to be small tend to grow into relatively large ones. The Space Test Program, operated by the U.S. Air Force for the Department of Defense, could provide a model for a renewed NASA effort to design a series of small-scale, productive missions that would remain small.

At the present time, funding allocation for post-mission data analysis is generally insufficient to permit optimal use of data returned from spacecraft. Relative to the total cost of a given mission, the cost of analyzing the data returned is small. Given the current practice of combining the budget for science per se with the budget for hardware, some have suggested a minor reallocation of mission funding, in which a modest reduction in overall mission capability would free additional funds for data analysis, as a way to ensure an improved scientific return. Alternatively, a base budget for science, including support for data analysis, might also solve the problem.

The budgetary situation of space science has been characterized by major fluctuations caused, in large part, by pressures originating in other areas of the space program. Planning for space science, therefore, even if it is extensive, is not necessarily effective over the long run. Every effort should be made to avoid situations in which plans are made on scientific grounds and then modified later on nonscientific grounds. At a minimum, the science will suffer; to the extent that expenditures have been made, there will also be monetary loss. In addition, because many efforts are interrelated, changing one may affect others, sometimes substantially. Finally, failure to see a project through to completion can adversely affect the careers of the scientists involved, often requiring them to reorient their research programs, and can damage the prestige of the Nation, particularly when international agreements are broken.

International cooperation in scientific activities has been fruitful in the past and, for possible major missions in the future, may be highly desirable in order to share costs. International partners, however, perceive a problem of the United States reneging on commitments to international missions, including commitments made by Congress. As a result, they are reluctant to enter future agreements with the United States. This situation is likely to continue until better assurance can be given that U.S. commitments made to international space science missions are honored.

POSSIBLE NEW DIRECTIONS

The current practice of budgeting most flight missions as independent new starts emphasizes spectacular accomplishments, and is not necessarily optimal for scientific progress. This practice has perhaps been perceived as necessary in the absence of a national commitment to particular space science goals. The alternative most often discussed—what might be termed the programmatic approach—differs in at least two respects.

First, budgets for important continuing activities (including instrument design, data analysis, theory, and perhaps small- to moderate-sized missions) would be separated from (and thereby protected from cost overruns in) the budgets for major missions (including hardware, launch, and mission operations). With this separation, scientifically valuable, but unspectacular activities could be sustained even in times when overall funds are strictly limited; missions to take advantage of unique opportunities could be supported as the overall budget allowed.

Second, missions for each discipline would be designed primarily in accordance with long-term scientific needs. Especially with a commitment to particular scientific goals, the programmatic approach might make the entire space science effort—planning, execution, and data analysis—more effective.

In the opinion of many space scientists it would be advisable to place the responsibility for scientific projects as nearly as possible in the hands of the principal investigators. The current management scheme for the Space Telescope Science Institute provides an interesting example (and test case) of how scientists themselves may undertake the long-term operation of a major research facility.

The boundaries that formerly justified NASA's being the lead agency for the space-based efforts in space science and the National Science Foundation's playing a similar role for those that are ground-based are becoming increasingly arbitrary. There is some indication that a cross-agency advisory mechanism would be useful in adjudicating jurisdictional questions that occasionally arise among these and other agencies responsible for various space science activities and in ensuring a balanced, nonduplicative space science effort. One possibility for addressing problems of coordination would be to broaden the charter of the Space Science Board (SSB) of the National Academy of Sciences to include determination of priorities of all activities in space science, not just those proposed for NASA.

The current crisis in space science might well be an opportunity for SSB to take stock of the details of the problems indicated in this technical memorandum. An initial task would be to give a clear accounting of the numbers of people engaged in space science, and of their distribution; analyses of the effects of reduced or level funding on research groups could be undertaken. Information relating to these matters is still largely anecdotal. Without this information, the present health of space science research in the United States cannot be precisely assessed, nor can its future needs be predicted.

Overall, it seems desirable for SSB or some other duly constituted body to begin a more thoroughgoing effort to set scientific priorities for space science within a framework of possible budgetary alternatives. If this were done in a context in which: 1) one budget would be set for continuing activities that are scientific per se, and 2) another budget for missions would be separately negotiated, scientific expertise might be brought to bear on the choice of space science activities more effectively.

Chapter 2

Current Situation in Space Science

Over the past quarter century the United States has developed a scientifically productive space science program. The largest number of missions have been dedicated to solar and solar-terrestrial physics; as a result of this sustained work, scientists are developing a good understanding of Earth's magnetosphere and its interactions with many solar phenomena. The Mariner, Pioneer Venus, and Viking missions have been flown to our neighboring terrestrial planets, Mercury, Venus, and Mars; Pioneer and Voyager spacecraft have returned a vast array of important and exciting data from Jupiter and Saturn in the outer solar system. The planned launch of the Space Telescope will increase our knowledge of the farthest reaches of the universe with imaging capabilities never before achieved in optical astronomy.

Over the past few years, however, there has been a significant downward trend of budgetary support for one subdiscipline* of space science, planetary exploration. (See app. A.) Recent budget cuts have now called into question the continuation, survival, and future viability of the U.S. planetary science program. In the view of the planetary scientists, the program is in danger of complete collapse. If the present trend in funding were to continue, the planetary science program would be extinct by the end of the decade.

In spite of the apparently greater resources at their disposal, problems confront solar and heliospheric physics, and X-ray and gamma ray astronomy, all of which have had their major missions deferred. Overall, only the launch of the Space Telescope and a possible repair of the Solar Maximum Mission remain in prospect. Indeed, there is no assurance that the United States will fly a major space science mission after the Space Telescope.

It was widely held in the OTA workshop that current funding for space science makes it impossible to maintain all the subdisciplines at viable levels. There is some possibility, however, that a relatively minor reapportionment in funding from hardware development to postmission data analysis could be a useful interim measure. Despite its best efforts to provide a balanced space science effort, the National Aeronautics and Space Administration (NASA) has found it necessary to reduce support in planetary research in an attempt to maintain previous commitments within the agency and to maintain the viability of the remaining projects.

Space scientists are especially concerned by four immediate problems:

1. lack of flight opportunity;
2. uncertain commitment to the range of disciplines;
3. lack of support for postmission data analysis; and
4. threatened loss of data from existing spacecraft.

None of the disciplines of space science escapes the threat posed by these elements.

The area of most pressing concern to scientists, however, has been planetary exploration, where effected or proposed funding cuts of 50 percent in mission operations and data analysis and 30 percent in research and analysis, between fiscal year 1981 and fiscal year 1983, are resulting in significant reductions in basic research in planetary science programs at universities and NASA centers; if inflation is taken into account, these cuts are significantly larger. Some research laboratories and institutes such as the Jet Propulsion Laboratory, which have been operating for many years, may have to direct their efforts into other fields.

These cuts have seriously threatened to terminate productive, active spacecraft (Pioneer Venus Orbiter and Pioneers 10 and 11). Because of the current situation in planetary science funding, no experimenter can with any reasonable degree of assurance foresee the time when his experiment, if selected, will fly; no laboratory scientist can feel confident that a new research project will be funded long enough to come to fruition.

*In this document the word "subdiscipline" is taken to mean any branch of recognized disciplines; thus, X-ray astronomy is a subdiscipline of astronomy.

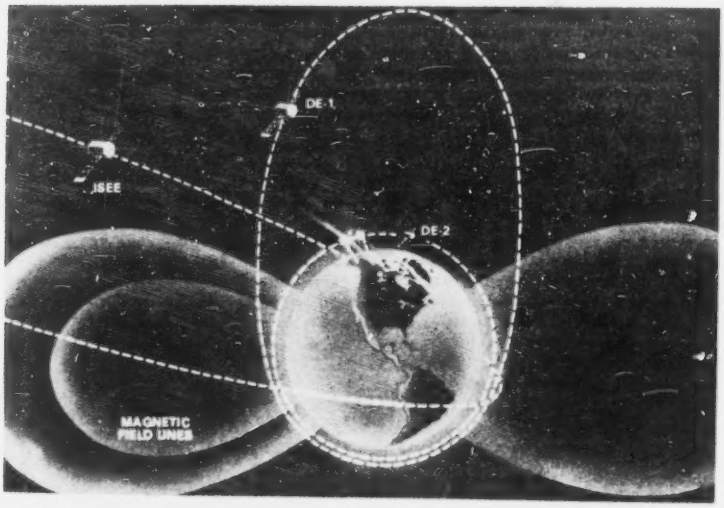
The Diversity of Space Science



By releasing visible metal vapors at altitudes of about 1,450 km, NASA scientists were able to measure the electric fields that cause auroras in the underlying ionosphere by accelerating charged particles along the Earth's magnetic field lines. Measurements were made Apr. 12 and 26, 1982, by particle detectors aboard two Dynamics Explorer satellites

Throughout space science this problem is compounded by the maturation of the several space science disciplines. At present funding levels, the frequency of new missions for each major discipline has already decreased to about one per decade per discipline. The disciplinary category of planetary exploration and the subdiscipline of X-ray astronomy are perhaps affected the most by this situation; solar-terrestrial research and the atmospheric sciences also are approaching a critical level of support. Increasingly, universities and industry are assessing the opportunities to be so minimal that they will no longer pursue them; as a result, experienced scientists are leaving these fields, and students and other new researchers are not entering them.

This situation has been caused in large part by a trend toward fewer, more expensive missions. During the earlier stages of the national space program, there was, at least in the astronomy and physics disciplines, a broad mix of relatively inexpensive science opportunities (including experiments on sounding rockets and balloons) and facilities-class spacecraft (Orbiting Geophysical Observatories, Orbiting Solar Observatories, Orbiting Astronomical Observatories, Interplanetary Monitoring Platforms, Pioneers, etc.). This mix allowed for an active, growing community to do important, productive work. If one group failed to qualify for flight on a major observatory spacecraft, it might still qualify for a small project, in which the group could still maintain productive activity and could develop plans for the next major opportunity. Today, however, failure to qualify for a major mission is extremely detrimental to the long-term continuity of the proposing group, for there are insufficient funds set aside for the smaller projects. (These include such important interim activities as analysis of data from previous missions.)

A number of problems have attended the development of large, sophisticated missions. For example, because the Galileo mission to Jupiter is dependent on the shuttle, delays in the latter, and its associated upper stage, have caused the former to be delayed as well. The delay in Galileo caused its funding to be stretched out, and ultimately increased its costs.[1] For another example, maintaining balance within a discipline becomes a problem when, given a relatively constant space science budget, increasing outlays for one project, particularly a major one like the Space Telescope, reduces the funding for others.[2] Space science has been affected also in that the number of flight opportunities on the shuttle has been decreased and in that those missions which require a high-energy upper stage have been indefinitely postponed.

Another important aspect of the current situation is that the United States currently enjoys scientific and technological leadership in most of space science, but in certain areas, e.g., cometary research and ocean remote sensing, leadership could soon pass to the Soviets, the Europeans, and the Japanese. Failure of the United States to mount a mission to Halley's Comet puts U.S. scientists at a clear disadvantage with respect to the Europeans and the Soviets, both of whom will be flying such missions. A similar situation prevails in oceanography:

> Japan presently has an ocean satellite under development, MOS-1, scheduled for launch in 1985; it will carry all passive sensors. The European Space Agency is in the final stages of authorizing funds for ERS-1, scheduled for launch in 1986 or 1987—it will carry active and passive sensors. Canada is interested in flying a Synthetic Aperture Radar (SAR) with another country in the late 1980's.[3]

Chapter 3

Issues and Findings

LACK OF POLICY COMMITMENT

A major difference between the National Aeronautics and Space Administration's (NASA's) space science program and its manned program is that the latter has developed in response to national commitments to particular goals such as landing an astronaut on the Moon before 1970 or developing a reusable space shuttle; space science has not been charged with meeting particular national goals, but has proceeded in accordance with its own priorities, at a much lower level of commitment.

Because of the central importance of this issue, it is desirable to reach a clear understanding of the different levels on which the United States can (or cannot) be said to have a space policy. At one end of the scale, the 1958 National Aeronautics and Space (NAS) Act is the foundation on which the U.S. space program now rests.[1] As a kind of constitution for the conduct of space activities, the NAS act articulates the principles in accordance with which particular national policy commitments are to be framed. These policy principles include that:[2]

- peaceful uses of space are to be developed;
- U.S. preeminence in space science and applications be maintained;
- knowledge be increased;
- economic and social benefits be derived;
- civilian and military activities be separated (though they are to be coordinated so as not to duplicate one another unnecessarily;
- NASA, the civilian agency, be limited largely to research and development (R&D); and
- international cooperation be fostered.

The NAS act neither specifies national policy goals nor provides guidelines for implementing particular programs.

At the other end of the scale are particular internal policies which NASA or any other agency may institute in order to carry out its mandated duties in an orderly and successful fashion. One example of such particular policies is that NASA maintains lead-agency responsibility for space-based astronomy, and the National Science Foundation (NSF) that for ground-based astronomy.

Between these two levels is that of national policy goals. Such goals are set at the highest levels of Government; they provide a direction, define the scope, or name targets for the Nation's space activities. In addition, a policy goal defines by its wording the relative importance of the activity. The most significant aspects of these goals are that they often command bipartisan support, that they outlast any given administration, and therefore, that they serve as pledges that the Nation will support the long-term conduct of the specified space activities. At present, no national policy goals for space science exist.

Without national commitments to particular science goals, waste and instability in the space science program have been unavoidable: 1) projects being planned have been substantially changed or reordered in priority (e.g., Galileo), 2) projects under development have been deferred or canceled (e.g., the Mars Voyager mission), and 3) projects in operation have been scheduled for early termination (e.g., the Apollo Lunar Service Experiment Package, ALSEP).[4] In addition, the absence of policy goals has meant that several important questions, the answers to which determine the characteristics of the space science program the Nation actually undertakes, are decided ad hoc. These questions include:

[1] National Aeronautics and Space Act of 1958 (42 U.S.C. 2451 et seq.), as amended.

[2] For a fuller discussion of these policy principles, see: *Civilian Space Policy and Applications*, OTA-STI-177 (Washington, D.C.: Office of Technology Assesment, U.S. Congress, June 1982), pp. 35-44.

[4] Part of the reason for these difficulties is that a commitment to science is usually understood to be a commitment of funds to a "new start." More conducive to the accomplishment of good science would be a view that a policy commitment entails commitment to a *program* of investigation (i.e., a series of related missions extending beyond the time when the instruments are successfully operating to include funds for data analysis and design of future experiments). For further discussion of a program approach to science, see *"New Starts" v. "Programs."*

98-704 0 - 82 - 3

- How may the goals of space science research be maintained vis-a-vis the objectives of a much larger manned space program?
- What is the proper mix of expensive, complex science projects and those that are simpler and less costly?
- How may international missions be undertaken effectively?
- How can the management of space science be improved?

The issues raised by these questions will be examined in the subsequent sections of this technical memorandum.

The key factor to be noted here is that in the absence of a national policy goal for space science, program decisions are determined by the size of the available budget. The reverse situation, in which policy determines budget, would probably be the more desirable, but neither Congress nor any recent administration has made a policy commitment strong enough to do so. If such a policy commitment were made, it would then be possible to set a base budget adequate to sustain the activities deemed essential to meeting the goals of that policy.

An advantage of adopting one or more national policy goals for space science would be resolution of the question of balance in the space science program. Traditionally, it has been thought that science as a whole progresses best when effort is rather evenly balanced among its parts. Maintenance of a balanced effort by means of an even spread of funding has, for example, been the cornerstone of NSF's support of science. Space science, however, forces a reconsideration of what balance in the program should mean, because some disciplinary areas (and the planetary sciences in particular) seem to have a higher threshold value for worthwhile missions than do others.

If a national policy commitment to a clear set of goals for U.S. space science were in place, space scientists would have a more realistic framework within which to set their priorities. Even without such a commitment, it is necessary, given NASA's limited budget, that scientists make a more thoroughgoing attempt to weigh scientific priorities against considerations of cost.

CONTINUITY, PLANNING, APPROACHES, COSTS, AND LIAISON

There are several problems in the space science program that result from causes other than the absence of policy goals. These causes include: modification of long-term planning in response to near-term crises, NASA's emphasis on "new starts," the accumulation of costs that may be unnecessary, and the need for more effective contact between the scientific community and the appropriate congressional committees and their staff. These problems are summarized in this section.

Continuity and Planning

Continuity is essential to the accomplishment of good scientific work; no scientist can respond efficiently to frequent, major perturbations. Continuity is particularly important when the Nation undertakes cooperative programs with other countries. The development of hardware and software and the training of personnel cannot be accomplished overnight. In addition, the cancellations and/or deferrals of programs (International Solar Polar Mission, Venus Orbiting Imaging Radar, Gamma Ray Observatory, Galileo, Origin of Plasmas in the Earth's Neighborhood, Upper Atmosphere Research Satellite, etc.) suggest to many young scientists, engineers, and technicians that the future of U.S. space science programs is now sufficiently uncertain that they should direct their careers elsewhere.

One step in addressing the discontinuities in the space science program would be to establish policies that would permit effective long-range planning. If such policies were in place, the program would be more stable because discontinuities would be minimized, if not eliminated. According to the workshop participants, achieving stability in the space science program, through effective implementation of NASA's long-range plans, is at least as important as raising the current level

of funding. The key term here is "effective;" NASA's long-range planning seems formally to be quite good, requiring few modifications. However, if there were a stronger national policy commitment to space science,* NASA's long-range planning would be less affected by instabilities deriving from extreme budget fluctuations** and by delays in portions of the manned program on which the science program is dependent.

Because space science projects require a decade of work from serious inception to significant funding, a good long-range plan should span 10 to 15 years. Within the general guidelines of any plan, however, flexibility must be maintained, first, because the priorities of science may change, and second, because budgets tend to fluctuate. Given that a base budget has been established as a matter of national policy, the plan could make provision for periodic adjustments resulting from those budget fluctuations. In general, the plan could be elaborated within two separate budgets, one for science per se, the other for missions, including hardware, launch, and operations. The first would establish a base level of continuing activities, all of which would be supported even in times when overall funds are strictly limited. The second would establish a set of initiatives, subject to revision in the light of scientific advances or because of changes in scientific priorities, to take advantage of unique opportunities as budget allocations allow. In particular, provision should be made that:

- a detailed subset of the plan extend over 3 to 4 budget years,
- all interested parties contribute to the formulation of the plan,*** and
- there be developed alternatives in the schedule and scope of the program that correspond to realistic alternatives in the final budgets.*

Finally, subject to full discussion and periodic review, the plan could incorporate decisions reflecting the balance to be struck among subdisciplines.

"New Starts" v. "Programs"

The current practice of designing most flight missions as independent new starts tends to emphasize the space spectaculars and to distort priorities of space science, thus reducing the efficiency with which its objectives are pursued. In many cases a more cost-effective method would be to support continuing programs, which might include small- to moderate-sized missions as part of the baseline, and to obtain new-start status only for the more expensive missions.

NASA's conduct of space science by means of spectacular, independent missions has achieved notable successes in opening new scientific domains to investigation. In addition to accomplishing much good space science, such missions are attractive to Congress and to administrations because they appeal to the public and because they add to the international prestige of the Nation.

Another characteristic of stand-alone new starts, however, is that they tend to be expensive. There is every temptation to make these missions as sophisticated as possible, rather than to design them to accomplish, say, 90 percent of the scientific objectives at 50 percent of the cost.** In times when the budget for space science is large enough to meet the major objectives of science, this method of conducting research presents few problems, but in the present era of more limited available funding, another method may be appropriate.

*Throughout this document, the notion of stronger policy commitment is to be distinguished from that of a greater funding commitment (i.e., larger appropriations); neither necessarily implies the other.

**To see that there have been extreme budget fluctuations, it suffices to consider the figures in app. A.

***It is important for all components of the space science establishment, Federal and non-Federal alike, to participate in the planning process. If all groups are invited to contribute to these discussions, those which may be adversely affected by the final outcome will have a better chance to adapt to their new constraints and will have less cause to complain. In addition, particular attention should be paid to interagency coordination. The importance of this topic warrants separate discussion, in see *International Concerns*.

*Given that budgets might vary from 5 to 10 percent above and below the planned levels, three alternative plans might be devised: one, in which the current level of effort is maintained, and one each for a 5 to 10 percent increase or decrease in the current level. If it is necessary for the budget to be cut, or possible for it to be raised, the existence of these alternative plans will facilitate making the corresponding changes in the program, with minimal wasted effort.

**To a first approximation, it is just as difficult to obtain commitment to a small mission as to a large one.

The major alternative is to conduct space science research programmatically—i.e., to emphasize the development of disciplines and continuity of operations rather than to emphasize new starts (see app. A). This approach might be realized by sets of several closely connected space missions or experiments, planned as integrated series, directed toward well-defined goals of the several subdisciplines, and supported by programmatic and budgetary continuity from inception through postmission reduction and analysis of data.

Funding Delays and Effects of Cost Uncertainties

Funding delays, wherever they arise, generate increased costs, and these, in turn, cause instabilities in program planning, leading finally to an instability in the program and the planning process.

One important aspect of program stability is sound implementation. If projects turn out to have been initially underbudgeted, or if they must be stretched out in order to accommodate budget cuts, their cost effectiveness decreases. The Galileo mission is an example where costs have increased substantially because of delays; the result is fewer missions or higher overall costs. Although current budget totals appear to compare favorably with those of the past, a larger portion of current funding in fact tends to go toward supporting unproductive work, as is the case with Galileo.*

*The labor expended in redesigning a mission for other than scientific reasons, particularly when it is done more than once, can hardly be considered productive.

The appearance of current budget totals (see app. A) is deceptive in another way: just as the Space Telescope is taking a larger portion of NASA's physics and astronomy budget, so Galileo is doing the same for the planetary science budget—a factor which makes the decrease in the overall total of the latter even more serious for other parts of the planetary program.

The Need for Adequate Discussion of Program Priorities Among Interested Participants

If they wish to take a more active role in setting national policy goals for space science, appropriate congressional committees need to have closer contacts with the space science community. Because of its scientific status, its representative character, and its relative independence, the Space Science Board (SSB) of the National Academy of Sciences could be the appropriate vehicle for improving the liaison between Congress and the community of space scientists. Especially if, as suggested in the section entitled *Management Issues*, its advisory responsibility is widened to include related activities within other agencies, SSB can present formally to NASA and informally to Congress an integrated program of space science priorities based on the process of peer review. Through annual discussions with SSB, or more frequently, if appropriate, congressional staff could, in turn, assist scientists in understanding congressional priorities and funding considerations.*

*A formal relationship could also be established between Congress and SSB. In this mode, Congress through its committees could ask SSB to carry out special studies, in which case Congress could be expected to contribute to SSB's costs. If this were done, SSB would be related to Congress as it now is to NASA: reports would not be delivered to Congress until they had been carefully reviewed and approved by the National Academy of Sciences through the mechanisms of the National Research Council. It would be desirable, however, for congressional staff to attend the nonexecutive sessions relevant to the studies, so that nothing in the final report would come as a surprise.

IMPACT OF MANNED SPACEFLIGHT—PRESENT AND FUTURE

Manned space projects arise as national political imperatives. Their total costs dwarf the science components that accompany them, and their impact on the space science program is substantial. Although scientists will learn to make good use of the shuttle, that vehicle is inappropriate and inadequate for certain kinds of research. Similarly, if a single permanent, manned space station is built, its architecture and orbital characteristics will to a large extent determine the kinds of space science research that can be done. For example, X-ray research needs a low-inclination orbit; solar terrestrial research and weather monitoring need high-inclination orbits. In general, a space station could be useful to science if: 1) a large enough research and analysis budget is set aside; 2) requirements for cleanliness and capabilities for pointing are met; and 3) access to orbits incom-

patible with the shuttle is assured (i.e., a commitment to an orbital transfer vehicle is made).

Many scientists believe that the United States should ultimately develop a permanent presence in space, centered on some type of manned space station, and that the need for such an effort will become more evident as the intentions and capabilities of other nations become clearer. In its planning for a possible space station, NASA has initiated extensive discussions with the Space Applications Board and SSB of the National Academy of Sciences to define the science and applications needs that a space station could meet. Scientists remain concerned that capabilities promised for a space station be in fact achieved, in order that situations may be avoided in which these capabilities—on which scientists have counted in planning and designing their experiments—remain merely virtual. Scientists are also concerned that cost overruns for a space station might, at least indirectly, reduce the funding available for the space science that cannot be done on a space station, or might result in a less ambitious project from which science capabilities might be excluded.*

Although most space scientists prefer to conduct experiments on unmanned flights, they will now have to tailor many of their projects to manned flights. To date, most space science experiments do not require the assistance of astronauts, whose presence adds greatly to the expense of missions. In the future, however, this situation may change. Already, the manned program has been very valuable to solar physics (e.g., in X-ray and ultraviolet photography of solar flares from Skylab) and to planetary science (e.g., in the selection of lunar samples), and it promises to be important for the life sciences. Eventually, astronauts may retrieve, repair, or refurbish scientific experiments, just as they may construct large space structures which hold promise for space research.

*Space scientists remain convinced that cost overruns on the shuttle have been a major cause of the problems now facing the space science program. See, for example, app. F.

General Problem of Big Projects

For purposes of this discussion, a dividing line between big and small projects within NASA might be set somewhere between $100 million to $200 million.* Small projects include unmanned,

*More accurately, there are four major mission categories: 1) small (<$100 million to $200 million); 2) large ($200 million to $750 million); 3) very large ($750 million to $1,500 million); and 4) manned missions. Explorers fit into the first category. The second contains missions such as Galileo, Voyager, HEAO, Landsat, and GRO. The third contains the Viking missions, the Space Telescope, and the proposed OPEN and AXAF missions.

This photograph of the Sun taken Dec. 19, 1973, by astronauts aboard Skylab, shows one of the most spectacular solar flares ever recorded, spanning more than 588,000 km across the solar surface

typically scientific spacecraft in the Explorer class; big projects include all the manned efforts as well as several important science and applications missions, including Viking, Voyager, and Landsat. In practice, the large projects are divided into two categories: those, like Apollo or Space Shuttle, which respond to a national policy commitment and those, like Galileo or Voyager, which respond to the priorities of particular communities of end users. To date, no unmanned missions have fallen into the first category.

Within NASA, missions of the first type are given priority over those of the second, and those of the second tend to receive priority over small projects. The scientific community is apprehensive, on the one hand, that large manned projects will increasingly call the tune for the entire space research program, specifically that science projects will be required to use the shuttle or a new space station, and, on the other hand, that large space science projects will draw funds away from smaller ones.

There are different points of view concerning the role of big projects within NASA. One point of view, reportedly shared by all previous NASA Administrators, holds that the agency's raison d'être is its large manned programs, and that much of what the agency has been able to accomplish in space research has been based on the existence of those programs. A contrary point of view, shared by a number of scientists, holds that the Nation would have recognized the importance of basic research in space and that the space science program would have been successful regardless of the presence of large programs like Apollo or the Space Shuttle. The rationale given for this second point of view is that space science and the techniques for accomplishing it have provided and may be expected to continue to provide the basis for most of the utilitarian applications of space technology.

The Nation's past and largely successful space science effort has been conducted with both large and small projects in progress at the same time. Just as there are fundamental questions in high energy physics that cannot be answered without large particle accelerators, and questions at the frontier of astronomy that cannot be addressed without large telescopes, so there are important areas in space science that can be opened for investigation only by large, sophisticated missions.

On the other hand, small space science projects (e.g., those conducted on balloons or rockets, laboratory investigations, data analysis, and instrumentation development) are important in at least two respects: first, it is uneconomical to employ large instruments to do what small instruments can do; second, the existence of relatively many small projects provides the overall scientific context of the field, from which new ideas and concepts originate. A space science program consisting only of small projects would, over the long term, produce results of decreasing interest; one consisting only of large projects would soon be unsupportable.

NASA is aware of these arguments and, by conducting large and small projects simultaneously as much as possible, has strived to maintain a balanced space research program. With the maturation of each of the disciplines in space science, with level or declining budgets, and with other large, costly projects within NASA, it has become increasingly difficult to conduct a well-balanced space research program. Since autumn of 1981, the large-scale science projects have been par-

ticularly under attack, for the elimination of one or more of them would free substantial funds for other programs.

Another consideration is that, in a situation of more limited funding, large space science missions can be flown less often, partly because the competing needs of the several space science disciplines call for higher percentages of the space science budget, and partly because the growing sophistication of the instrumentation on these missions tends to make them more costly. Indeed, the frequency with which they are flown has decreased to the point where major groups within industry and in U.S. universities that are necessary for a successful, long-term space science program are being disbanded.

In summary, large science projects are necessary to sustain scientific progress, but tend to crowd out smaller scale projects, and, given current budget constraints, they have been mounted less often than required to maintain space science teams. In the present situation of level overall funding divided among fewer, but generally more expensive activities, an increasingly heterogeneous space science community has been forced into a mode of divisive competition for available resources. The diversity of the community, set in the context of constrained funding, makes consensus on priorities set by means of broad-based peer review especially difficult to achieve. Thus, officials at NASA, whose responsibility it is to make these decisions, face growing difficulties. A good solution to this complex set of problems is not yet evident.

Costs of Shuttle Payloads

During the past decade, the United States has spent some $20 billion for development of the space shuttle, which is the fundamental component of the Space Transportation System (STS). Advocates of this development have maintained that STS will: 1) advance the Nation's technological competence in space flight, 2) make it feasible to continue manned flight, and 3) reduce the cost of launching scientific and applications payloads (below the cost of launches on expendable unmanned launching systems), and thereby greatly expand the practical uses of space technology. The first and second of these objectives

Photo credit: National Aeronautics and Space Administration

Launch of the space shuttle Columbia

seem well served by the shuttle; the verdict on the third is not yet clear.[3] The whole question of how shuttle costs ought to be calculated is vexed. NASA's current policy is to recover from users only the marginal operating costs of shuttle flights, not total operating costs. (See app. D for a comparison of shuttle and expendable launch vehicle (ELV) costs.)

Constraints Imposed by the Shuttle

Use of the shuttle, both because of what it requires and because of what it can and cannot ac-

[3]See, for example, Daniel Deudney, "Space: The High Frontier in Perspective," Worldwatch Paper 50, The Worldwatch Institute, August 1'82: "The reusable space shuttle, first tested in 1981, was expected to accelerate the exploitation of space by reducing the cost of putting an object into orbit and allowing the repair or retrieval of orbiting satellites. However, [because of] funding delays and cost overruns it now appears that the shuttle will be only marginally cheaper than the new generation of expendable rockets." See also app. E for an analysis of shuttle economics by James A. Van Allen.

complish, has a significant impact on space science. Experiments to be conducfed on the shuttle require extensive documentation because they must all be man-rated, (i.e., certified not to endanger the crew). This requirement presents an unwelcome and inconvenient barrier to scientists, and raises costs. As more experience is gained with the shuttle, however, documentation requirements for man-rating may be eased.

The brief time of a shuttle flight presents another problem for scientific experiments designed to be conducted on the shuttle. In many investigations, a shuttle flight is scarcely long enough to provide a check-out of the equipment and provides modest results when compared with really long-term temporal and spatial coverage—often for more than 2 years—with free-flying satellites. In addition, if space science is not to be limited to those orbits accessible to the shuttle, one or more high energy upper stages or perhaps one type of ground-launched, ELV will be needed to supplement the shuttle's capabilities.

The shuttle is especially appropriate for space science missions that do not require long durations in orbit, that require a heavy payload to be placed in low Earth orbit, or that can fly in shuttle orbital inclinations. Observational astronomy and Earth observational experiments can benefit from the shuttle more readily than can other disciplines. On the other hand, the present capability of the shuttle is incompatible with the needs of some scientists (e.g., atmospheric scientists who require a polar orbit, or planetary scientists who require high-energy stages for interplanetary probes). However, with greater frequency of shuttle flights, launches into polar orbits from Vandenberg Air Force Base, and the development of an appropriate upper stage, this particular problem may diminish over time.

Concerns Regarding Military Use of the Shuttle

There is a general concern throughout the civilian community that military requirements may begin to dominate the shuttle's budgets, flights, and schedules. There is a similar concern that if a space platform is built, the military would preempt it, crowding out possible uses for science.

Recently, the U.S. General Accounting Office (GAO) has reported[4] that of the 234 shuttle flights scheduled through 1994, 114 of them (i.e., 48 percent) are dedicated to the Department of Defense (DOD); in the nearer term, 13 of the initial 44 flights through 1986 will be exclusively military. Not only will DOD be NASA's single largest customer, but also, at least through 1986, when user fees for the shuttle are to be renegotiated, NASA may be charging DOD substantially less per flight than it charges civilian users—$12.2 million as opposed to $18 million, a discount of 32 percent. In addition, it seems likely that NASA will be doing substantially more work for the military, and that the Jet Propulsion Laboratory, which has been heavily involved with NASA's planetary science program, may return, for the most part, to its earlier support role for the military.[5]

[4] "NASA Must Reconsider Operations Pricing Policy to Compensate for Cost Growth on the Space Transportation System," a Report to the Congress by the Comptroller General, MASAD-82-15 (Washington, D.C.: U.S. General Accounting Office, Feb. 23, 1982).

MIX OF SCIENCE EFFORTS

Mission Complexity

Over the years in which the United States has been conducting space science, a broad range of mission types has been flown—from relatively simple experiment packages carried by sounding rockets and high-altitude balloons, to the highly complex Voyager flybys of Jupiter and Saturn. Now that funds to support space science have, overall, been on the decline since 1974 (see app. C), it has become necessary to make certain difficult choices as to which future missions, and even which types of future missions, are to be supported.

As space science matures, missions tend to grow more complex and expensive. As missions grow more costly, fewer can be flown, given a constant or decreasing level of funding; but as flight opportunities are cut back, there is a tendency to make the remaining missions more complex (and, usually, more expensive). Some program officers at NASA believe that the era of small-scale missions is mostly passed—that to obtain scientifically useful results now requires sophisticated (and

Photo credit: National Aeronautics and Space Administration

Artist's conception of the descent of the Galileo probe into the atmosphere of Jupiter

costly) missions. It has become more and more difficult to mount small-scale missions, with the consequence that fewer sustaining activities are available between major flight opportunities.*

In view of the difficulty of planning and executing a balance of large- and small-scale missions in planetary science, NASA has established the Solar System Exploration Committee (SSEC). The charge of SSEC is to recommend to NASA an ordered, affordable program of exploration of the solar system.

*Two committees of SSB—the Committee on Space Astronomy and Astrophysics, and the Committee on Solar and Space Physics—are currently examining these issues.

There is disagreement about whether large or small missions are the more cost effective, and a detailed analysis of this question is beyond the scope of this study.* Similarly, the question of whether the Nation's broad technological base would be strengthened by a policy of funding more small missions is difficult to resolve. Basic agreement, however, seems to exist on the position that a range of missions makes the most scientific sense. Not only will the small missions pro-

*Often a debate about cost effectiveness degenerates into a dispute about costs. It is tautological to assert that large missions cost more than small ones; the real question involves the amount of science returned per dollar of outlay. (The probability that quality of science differs from quantity of science is another complicating factor.) The absolute increase in launch costs, which translates into an increase as a proportion of total mission cost, has become a dominant factor in such calculations.

98-704 O - 82 - 4

vide a continuous level-of-effort when budgets are low, but these types of small expenditures, including the funding for laboratory work, will lead to interesting and promising new laboratory techniques and other new instrumental approaches.

If NASA were to revive small-scale scientific missions, some sort of safeguard would be necessary to allow at least some of them to *remain* small. One possibility would be to adopt some version of the strategy employed by the Department of Defense (DOD). The U.S. Air Force has been designated as the service responsible for coordinating much of the unclassified space research for DOD, and it does so through the Space Test Program (STP). A scientist who is interested in flying an experiment on an STP mission submits a proposal without knowing to which mission it will be assigned. Both university-based scientists and those at Government labs may compete for space on a mission.

Experiments are selected for utility and relevance to the DOD mission. Once the experiments have been ranked within each DOD lab, STP selects a compatible set of lab and university-based experiments for flight on a mission for which one or more DOD experiments have the top priority. There is an average of six or seven experiments per flight, together with the experiment(s) for which the flight was chosen. As of spring 1982 there have been 32 STP flights. Currently, the average is one flight per year. The cost for an STP flight is comparable to that of an early-day Explorer mission.

Scientists who have experience with STP cite several advantages that it provides:

- minimal documentation;
- minimal oversight and review procedures;
- emphasis on low-cost missions;
- willingness to stand by decisions, with no rescoping;
- willingness to accept experiments with a relatively high risk of failure; and
- possibility of short turnaround times for some types of experiments.

There are, however, some generally perceived disadvantages. These include:

- orientation toward narrowly conceived missions;
- inadequate support for postflight data analysis;
- uncertainty of launch time and possibility of long waits in the queue;
- poor cross-checking of experiments for payload compatibility; and
- a failure rate higher than that of NASA.

For the needs of space science, the general negative feature of STP is that it supports isolated missions rather than basic research programs.

Some features of STP appear to be attractive for the support of small-scale missions; some of its procedures might be adopted by NASA in cases where they would be appropriate. Another possibility would be for NASA actively to promote, through wider publication and support, the flight of experiments in which it is interested on STP missions. STP offers some segments of the scientific community an alternate way to fly an experiment at low cost and with few restrictions.

Funding Allocation for Data Analysis

Compared with the costs of the actual mission (including launch vehicle, instrumentation, mission operations, and support facilities and personnel), the cost of postmission data reduction and analysis is minor. Even so, according to recent independent reports of SSB and GAO, the funding set aside for data analysis is inadequate.[a]

NASA's emphasis on supporting new starts has tended to concentrate attention on hardware and operations, rather than on the total scientific project. Consequently, proper attention to the problem of data analysis has not been given beyond that required for the major, relatively easily achieved initial results of the experiment. There is, however, more science to be gained by allocating an additional small percentage of the total cost of the mission to further data analysis. Continued examination of the data can still yield im-

[a]According to GAO, "the Congress should examine the adequacy of NASA's allocation of resources between gathering space science data and analyzing it. Greater emphasis is needed during the data analysis phase of a program to obtain the maximum scientific benefit from the data obtained." ("More Emphasis Needed on Data Analysis Phase of Space Science Programs," a Report to the Congress by the Comptroller General; PSAD-77-114; June 27, 1977). See also the CODMAC report of SSB ("Data Management and Computation, Volume 1: Issues and Recommendations," National Adademy Press, 1982).

portant scientific advances as new techniques for analysis are developed, existing techniques are refined, and increased understanding of the underlying physical processes is acquired.

Postmission data analysis is often the lifeblood of university space research groups. If NASA places more emphasis on this activity, these groups will be better protected in times of more limited budgets; data analysis is a type of activity that can be conducted with success, regardless of the level of the overall budget. At present, however, follow-on data analysis for the lunar and Martian missions, as well as for those of several subdisciplines (e.g., X-ray astronomy), is funded below the level at which the activity can remain viable. If all scientific activity is not to cease in those areas of research which will have no missions for the foreseeable future, then a base level of funding for data analysis must be maintained.

In addition, there is a need for data from past missions to be correlated over a long time sequence in order to corroborate the findings of independent missions and/or experiments, as well as to facilitate syntheses unifying results from related fields of science. Past results are often the key to understanding in the fields of solar physics, solar-terrestrial relations, and atmospheric physics, all of which require that data obtained over many years be compared in order to understand the basic processes in the Sun and in the Earth's weather and, in particular, to discover cyclic phenomena.

Archiving of Data

Whether or not data returned from space missions should be archived depends on several factors, including that of costs v. benefits. Because space missions are very costly, and the data returned from them correspondingly valuable, data should be archived if they are likely to be lost, if the cost to repeat the experiment is sufficiently large, if a long time base is crucial for the success of the project, or if the data might be unavailable when required. Too often, however, data may have been archived as an alternative to timely analysis.

One technological development that may go far toward solving the problems of data archiving is the new laser-read video disk. All the data returned from the Voyager missions to Jupiter and Saturn could be stored on disk and made widely available to scientists for a few hundred dollars. An investment in technology will still be needed to realize this possibility, and it will still be necessary for a calibration program to be included on each disk in order to make the data most usable to other researchers.

INTERNATIONAL CONCERNS

International cooperation promises scientific, cultural, economic, and social benefits to all participants. Over the long term, the prospects for international cooperation in space science ventures look very good. In general, it seems clear that missions that would be too expensive for the United States to mount alone could be undertaken with international support. The space programs of the Europeans and the Japanese have now sufficiently matured to permit them to become substantial partners in joint missions. While the current international situation tends to minimize East-West interactions in high-technology fields, the Soviet Union is quite active in space research activities, and it would be to the Nation's advantage to cooperate in some areas where the U.S.S.R. is clearly the leader--e.g., in the life sciences. In the past, international science projects have been one of the most effective means of making contacts across cultural and political barriers.

In the short term, however, prospects for major cooperative efforts are not so bright. Cancellation of the U.S. spacecraft in the International Solar Polar Mission argues that the United States and the U.S.S.R. are unreliable partners. If Spacelab-6 (to which Canada has already committed substantial funds) is also disapproved, foreign governments will be even less likely to agree to international ventures with the United

States. In any case, there seems to be little possibility for cost sharing on the missions in the immediate future, for most of them are already planned and do not include foreign partners. A more feasible form of cooperation for the near term is that of coordinated spacecraft launches, such as the International Sun-Earth Explorer missions, where each spacecraft is fully prepared by a single nation; in such cases, the scientific benefits derive from the sharing of data. However, the decision not to fly an appropriately designed mission of this sort to Halley's Comet, in coordination with the Giotto spacecraft of the European Space Agency (ESA), represents another lost opportunity for international cooperation.

In general, a more effective mode of cooperation must be devised that will allow two or more nations jointly to plan and execute space missions with minimal difficulties. There are two particular concerns that should be addressed. One is that commitments which the United States makes to international ventures should, if at all possible, be kept. Nothing will more effectively prevent future joint missions than a U.S. record of broken agreements. Cancellations of U.S. commitments to international space ventures may be necessary for budgetary reasons, but such cancellations indicate uncoordinated budget planning and the lack of concerted, bipartisan support for space exploration. It would seem fruitless to urge that, in order to avoid such cancellations in the future, commitments to international missions should be made at higher levels of authority, for some of the international commitments on which the United States has reneged were made by Congress. Nevertheless, it would be desirable to devise some means of assuring that U.S. commitments are honored.

The second concern is that, whereas NASA has allowed foreign experiments to be proposed for inclusion in U.S. missions (e.g., 20 percent of the instruments on the Space Telescope are Euro-

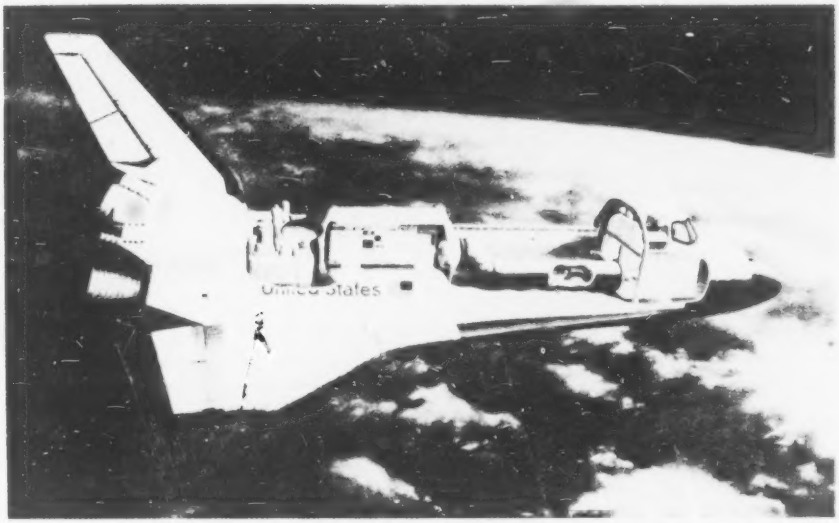

Photo credit: National Aeronautics and Space Administration

Artist's conception of Spacelab in the cargo bay of the orbiting space shuttle

pean), foreign organizations have generally been opposed to including U.S. experiments on their spacecraft. Now that foreign programs have in important respects become competitive with those of the United States, there is less need for them to protect their missions from possible dominance by U.S. teams of experimenters. In response to U.S. pressure for an appropriate quid pro quo in order to redress this imbalance, ESA, at the urging of the Space Science Committee of the European Science Foundation, has recently begun to formulate a new policy to address this problem.

From the U.S. point of view, increased participation in foreign missions is desirable. First, it obviously costs less for a U.S. team of scientists to pay the incremental costs of participating in a mission whose major costs (for design of the mission, for the launch vehicle, and for various support services) are borne by a foreign agency, than for the United States to develop and fly a comparable mission. Second, U.S. scientists find the cross-fertilization of ideas which results from participating in foreign missions to be very valuable. Nevertheless, if the level of U.S. participation in foreign missions does increase, the Nation should be prepared to provide the travel and other mission support costs that will be necessary to assure the success of that participation.

One difficulty for international cooperation in science surfaces when foreign experimenters participate in U.S. missions, for acceptance of a foreign proposal in a given subdiscipline necessarily reduces the support for U.S. teams competing in the same subdiscipline. Another problem is that NASA does not have well-understood and uniform procedures for funding U.S. co-investigators on European missions.

In summary, the prospects for international cooperation on large-scale projects, which the United States would find it difficult to fund alone, appear to be promising. Before an international venture is begun, however, it should be assured that all partners will gain by the cooperation, that it can be carried out with the backing of all participants throughout the lifetime of the project, and that the additional administrative costs that will be incurred are acceptable.

MANAGEMENT ISSUES

Management Alternatives

To date, most of the support for space science research has come from NASA, though DOD has funded much classified activity as well as the relatively small STP effort, and NSF supports work in ground-based astronomy and some data analysis and theoretical work in solar-terrestrial space physics. As space science has developed into well-defined disciplines and subdisciplines, requirements for flights to further their research programs have multiplied. Because of the high cost of its scientific missions relative to the cost of related science projects within DOD or NSF, NASA has a greater problem as it considers whether its missions will be supported by Congress and be appealing to the public.

It has been suggested that NASA should place more responsibility for space science experiments in the hands of principal investigators and to assign responsibility for future space science operations to organizations like the Space Telescope Science Institute (STScI). Another more radical suggestion has been to establish a separate agency, with a structure parallel to that of NSF, whose responsibility would be to support large, more costly, scientific enterprises such as space science research and high-energy physics. The general rationale for these suggestions is that NASA is chartered as an R&D agency, not an operations agency, and that the orderly progress of science requires commitment to continuing operation of scientific facilities. Both of these suggestions require comment.

Although there are good individual scientist-managers, not all scientists are good managers. As long as the science is not costly, and risks can be taken, there is considerable advantage in diversifying managerial responsibility. However, when costly, large projects are undertaken, the Government will generally institute procedures to make

38-036 O - 84 - 18

success more certain. These procedures lead to more oversight and tend to separate the scientist from his experiment.

The growth of "big science" has led to the establishment of national centers in astronomy, of which STScI is one example. Patterned after its successful ground-based counterparts, STScI is an example where managerial responsibility has been placed in the hands of the space science community. NASA set up STScI at the urging of the scientific community, although NASA's success in managing the International Ultraviolet Explorer indicated that it could have managed the Space Telescope quite effectively. In any case, STScI promises to satisfy the desires of the space scientists to have a more active management role in space research than they have had in the past.

At first sight, the establishment of a separate agency to support large scientific enterprises appears to have merit. As noted above, large projects require a different type of organizational management and more personnel than do small projects. Although concentration in a single agency would group large science projects, it might later destroy much of the internal balance and coordination between large and small science that currently exists within NASA and the Department of Energy (DOE). The new agency could easily become a target for budget cuts on the premise that a small percentage cut would still permit the science to be done, but would be the source of significant amounts of funds.

Distribution of Talent and Resources

So far, the space research programs conducted within NASA, at universities, and in industry have been rather evenly supported. The U.S. space science effort is truly a national program, and the distribution of resources and capabilities throughout the country has resulted in a reasonable balance. If, however, budgets for space science research remain constrained, then the possibility of an imbalance in the distribution of talent becomes greater because university and industry teams increasingly will have to be disbanded. It is important that a reasonable balance be maintained: healthy competition among researchers within NASA, at universities, and in industry has produced and will continue to produce the best science. Each leg of this triad has particular strengths, requirements, and/or responsibilities:

- Many of the new ideas for research originate within universities; in addition, the independence of university teams is vital to the process of correcting imbalances in the program if they should occur.
- NASA teams need sufficient work to maintain a reasonable level of competence because they manage the projects and provide valuable firsthand experience necessary for successful missions.
- As builders of most of the complex spacecraft systems, industry teams are crucial to the survival of an experimental space science. It is already the case that much of the complicated hardware for sophisticated missions cannot be built except with the expertise to be found in industry. There are too few civilian space missions to provide substantial profits for any company, but industry desires to participate in the civilian program because of the positive influence of space research activity on recruiting and retention of staff and on corporate image.

A further problem resulting from recent budget cuts is that, in order to retain key technical personnel, NASA may be assigning them to relatively unproductive oversight roles. This may lead not only to further loss of key personnel, but also to an overassignment of oversight tasks to the people who remain, even though there are fewer programs to administer. However understandable this response to a difficult budgetary situation may be, it is wasteful of resources, and in the long run, it may be detrimental to the morale of good scientists and engineers who would prefer to work in a more strictly scientific capacity.

Toward a More Effective Program

With time, the boundaries between space- and ground-based astronomy are becoming less well defined. The division of Federal funding wherein NASA has the lead agency responsibility for space-based astronomy and NSF that for ground-based astronomy is becoming arbitrary, for scien-

tists increasingly need to conduct both types of research in the ordinary course of their studies. As a result, it has been suggested that NSF should assume a larger share of postmission analysis of space-derived data and that NASA should fund a larger share of ground-based research that is of interest and importance to its overall mission. If this course is to be taken, the Office of Management and Budget (OMB) could assume the responsibility for assuring that the balance of funding available to these two agencies would allow a more effective partnership to develop in the Federal funding for space- and ground-based astronomy than that which currently exists.

A similar problem has been indicated by the Astronomy Survey Committee report of the National Academy of Sciences,[7] namely that the support for ground-based astronomy provided by NSF is not keeping pace with the support for space-based astronomy provided by NASA. In order to correct this imbalance, $40 million (in 1982 dollars) would have to be added to the NSF astronomy budget. The Solar-Terrestrial Physics report of the National Academy of Sciences also shows a relative lack of support for ground-based activities. In general, whereas at least the physics and astronomy portion of NASA's space science budget has continued to increase in recent years, NSF has been unable to make any new major capital expenditure decisions in astronomy for over 12 years.

Scientists generally do not believe that existing coordinating mechanisms are very effective. They do not see evidence that coordination is occurring at the higher levels of the agencies; some of them doubt that it occurs sufficiently at lower levels. One widespread opinion holds that OMB or the Office of Science and Technology Policy should take a more active role in interagency coordination, if only to set up a formal cross-agency advisory mechanism.

Some type of cross-agency advisory mechanism might be useful, for example, in resolving potential jurisdictional disputes and coordinating situations where one agency may wish to assume new responsibilities, to relinquish previous ones, or to exchange some of its current ones for others belonging to another agency. If an effective mechanism of this kind had been in place, the recent budgetary uncertainties involving the responsibility for funding the Infrared Telescope Facility in Hawaii might have been averted.

Another means of addressing the problem of interagency coordination would be to broaden the responsibilities of SSB to include oversight of NSF's activities in solar-terrestrial physics, astronomy, and some atmospheric research, as well as space-related activities of other agencies. As the major existing scientific advisory body for space research, SSB presents recommendations only to NASA. If, however, the purview of SSB were broadened, then its recommendations to NASA would be more likely to be based on considerations of disciplinary continuity across agency boundaries. Such continuity would help to ensure a more balanced Federal program in space science.*

In addition, it may be desirable to broaden the charter of SSB in another direction, namely, to give it the responsibility for combining priorities of space science with considerations of cost. If this is done, several considerations must be kept in mind. First, SSB, by virtue of its role within the National Academy of Sciences, operates in conjunction with an extensive process of peer review, and, hence, cannot do short-term problem-solving. Second, the space science community is quite heterogeneous (as is SSB itself); space science, properly speaking, covers a broad range of disciplines, each of which has its own set of

[7] George B. Field, report of the Astronomy Survey Committee, *Astronomy and Astrophysics for the 1980's* (Washington, D.C.: National Academy of Sciences, 1982). It should be noted, however, that this report does not treat the entire range of space science disciplines.

*On the other side it must be said that NSF's Astronomy Activity Committee already provides guidance in the area of astronomy and takes the space science activities into account. The National Academy of Sciences has found it necessary to maintain separate committees for space physics and solar terrestrial research, even though they address the same subject matter, because the modes of operation for space- and ground-based research are rather different.

In audition, such broadening of SSB's responsibilities could make it into an unwieldy bureaucracy. In each subject area in which this were done, the relevant committee of SSB would have to assume additional responsibilities, and SSB itself would have to assume more of an oversight role and less of a coordinating role. All of this would be possible only if quite a number of different offices in several different agencies consented to be advised in this manner.

priorities. Third, as contrasted, for example, with the organization of high energy physics into three or four cost centers, space science has many cost centers; it is big science, but it is not so heavily concentrated. For these reasons, SSB cannot be expected to function in the same way as does the High Energy Physics Advisory Panel (HEPAP), a scientific advisory panel of the Department of Energy.*

The heterogeneity of space science complicates the choice of priorities. Given NASA's division of space science into:

1. physics and astronomy,
2. planetary sciences, and
3. life sciences,

and assuming, further, that in each of these divisions subsets of SSB can meaningfully rank potential projects, it is nevertheless true that the assignment of a single absolute priority for all of space science from among the top ranked projects in each division is *not* a scientific decision. Such a decision is essentially political, based on considerations of what Congress is likely to support or what is needed to maintain balance among the disciplines. Space scientists are not notably more qualified to make such a political decision than is any other community.

An essential element in making this situation more tractable is to make a clear separation between the activities that are purely scientific and those that are, more strictly, engineering. In the past, the funds for the latter have far exceeded the funds for the former, and each division of science within NASA has had to pay for its missions out of its own budget. For reasons detailed earlier, big science missions—i.e., the engineering activities (hardware development, launch costs, and mission operations)—tend to consume the resources for small science—i.e., the continuing activities that are scientifically significant (including data analysis, theory, experiment design, and perhaps small to moderate missions for which hardware costs do not entirely dominate). If these budgets were separated, then SSB could very well make recommendations for setting the level of the nonmission budget, which would support the continuing science efforts of each of the space science divisions.

The level of the hardware budget, because it would have a strong political component, would be much more complicated to set. In general, because there would be a series of missions, each dedicated to one or more disciplines or subdisciplines, the level of this budget would vary rather widely, depending on the point of the mission cycle. SSB could function with respect to this budget much as it does now; i.e., it could continue to make recommendations for major missions corresponding to projected increases in available funding.

The current crisis in space science might well be an opportunity for SSB to take stock of the details of the problems indicated in this report. There is, for example, no clear accounting of the numbers of people engaged in space science, or of their distribution; data concerning the precise effects of reduced or level funding on research groups are still anecdotal. Without this information, the present health of space science research in the United States cannot be precisely assessed, nor can its future needs be predicted. This information would be especially useful for determining what an optimal base budget for space science would be.

*Overall, the HEPAP model is not a good one for SSB. High-energy physics is a rather narrowly defined scientific area with a small range of potential initiatives that have been well studied and costed. SSB and its committees, on the other hand, deal with areas in which costs are usually vaguely defined, although they make use of whatever cost information is available.

Chapter 4

The Importance of Doing Space Science

INTRODUCTION

Over the past 300 years, accelerating advances in scientific theory and practice have aided man in remaking the world. As scientific descriptions of our surroundings become more detailed, the practical consequences of applying scientific results and techniques to the problems of everyday life become more far-reaching. As the effects of science move out of the theoretician's study and the experimenter's laboratory, it is important to reflect on the reasons for undertaking science at all. It is not in the province of this report to justify the national effort in science, but it is nevertheless appropriate to discuss the importance of the space science program as a component of all Federal expenditures. Indeed, much of the rationale for doing space science is a corollary for doing science in general.

Space science is an undertaking that satisfies the visionary and exploratory needs of the human race. "In the future, as in the past, our freedom, independence and national well-being will be tied to new achievements, new discoveries and pushing back frontiers."[1] It is a cultural as well as a scientific activity that seeks to understand the Earth's place in the solar system, the solar system's place in the Milky Way Galaxy, and our Galaxy's place in the Universe. In assisting man to gain a better understanding of his place in his surroundings, space science also explores the fine structure of the universe in the form of samples, either examined in situ or returned for study on Earth.

At the bottom of the Earth's atmosphere, our ability to sense the universe is restricted to the visible and radio portions of the electromagnetic spectrum, but our extended ability to observe from above the atmosphere by means of instruments aboard spacecraft has widened our scientific vista enormously, and has permitted observations to be made of celestial objects that could not have been made in any other way. We are now truly viewing the universe through a set of multispectral eyes.

Astronomy is only one of the fields of science of which instruments aboard spacecraft have revolutionized our understanding. Others include the physics and chemistry of the Sun; energetic particles; the interplanetary medium; and the planetary sciences, whose purview properly includes Earth, as well as the Moon, the other planets and their satellites, and comets and asteroids. These fields have immediate importance for life on Earth. In fact, solar terrestrial physics and the planetary sciences as conducted from space have provided the basis for many of the important utilitarian applications for space technology—communications, navigation, meteorology, atmospheric physics.

EXPENSE OF SPACE SCIENCE AND THE ROLE OF PUBLIC SUPPORT

Increasingly, there are those who believe that the pursuit of expensive science solely for the sake of understanding, particularly in the face of other urgent problems facing mankind, may not be defensible. Because an expensive science project is a social product that depends on the common labor of many scientists, and because tax money must be allocated to support such an activity, the decision to pursue an expensive project and to allocate resources to it among competing alternatives necessarily entails political oversight.

More than ever before, a successful scientific career now depends on the support of public and private institutions. The days when individuals of independent means could make fundamental advances in science have mostly passed. The expense of pursuing fundamental research, particularly in the areas of so-called big science (e.g., high-energy physics, astronomy conducted with large telescopes, or space science), places these activities beyond the financial means of individuals. The costs of adequate scientific instrumentation are, for the most part, not borne by those who are to use them, but by Federal, State, and private laboratories—and ultimately by society as a whole. Thus, there is a kind of social contract between scientists and society, in which the pursuit of knowledge is exchanged for economic support.

Although the results of science have become part of our common heritage, the practice of science is becoming more and more a cooperative enterprise. Even though the individual genius will always be important in the process of scientific discovery, especially in purely theoretical work and in the practice of small-scale science, teams of scientists engaged in large-scale research projects are now quite common.

If society agrees to support science, the problem of just how that support should be apportioned remains complex. First, the very progress of science often leads to the need for more powerful instrumentation, especially in space science. As our understanding becomes more detailed, additional subdisciplines are founded, and each of them requires continued public support if it is to advance further. At the same time, other subdisciplines may be terminated, either because they reach a natural close or because they become too expensive to pursue further. In general, however, a situation where overall funding does not increase requires that some projects be delayed, stretched-out, or dropped, if others are to be supported.

Second, it is not possible to predict which scientific research programs will lead to improvement in the quality of human life. Applied science and engineering are undertaken with a view to producing relatively near-term benefits, but their productivity will soon become exhausted if a broad-scale program of basic research is not sustained.

It is important in this context to distinguish between *further* or *continued* research at a more or less constant level of funding and *expanded* research at a higher level of funding. In this report, OTA examines what value space science research has had in the past and is likely to have in the future, and what difficulties have arisen in maintaining a research effort at more or less constant overall funding levels; OTA has not considered the desirability of increasing funding levels for space science.

EARTH AND THE PLANETARY SCIENCES

The pursuit of planetary science has been of substantial importance to many of the geosciences, including geology, geochemistry, geophysics, geodesy, cartography, and photogrammetry. Exploration of other planets has returned results fundamental to understanding the evolution of Earth. These results derive, in large part, from the study of the crustal features and inferences about the interior of terrestrial (i.e., Earth-like) planetary bodies, including Mercury, Venus, Mars, and the satellites of Jupiter and Saturn.

The two principal drivers of planetary evolution are tectonism and vulcanism. Tectonism, the

processes that determine how the crusts of planets deform and buckle, is important to understand for purposes of predicting and giving early warning of earthquakes; research into vulcanism, the processes whereby molten portions of a planet's interior emerge onto its surface (either on the seabed or on land, in the case of Earth), is a subject of practical importance because further understanding may eventually lead to prediction of volcanic eruptions.

Both earthquakes and volcanic eruptions remain major hazards in many parts of the world. The thorough devastation resulting from the recent eruption of Mt. St. Helen's in Washington State and the great loss of life in recent earthquakes in Italy and Central America attest to the power of these processes and their consequences for human life. Planetary science is providing revolutionary insight into these processes. The hyperactive vulcanism on the Jovian satellite Io, for example, follows an entirely different pattern from that of the Earth; study of these differences may be the key to understanding how volcanic processes work.

Planetary science, by furthering our understanding of the processes whereby mineral deposits are formed, may provide unexpected assistance in evaluating, seeking, and discovering these resources on Earth. Extensive research on Earth has revealed that mineral deposits are unevenly distributed; a fundamental problem in plate tectonics—the theory of how the continental land masses slowly move over the Earth's surface—is to explain the peculiar distribution of these deposits. Many of them are very ancient, formed when Earth was more like the Moon, Mars, or Venus;

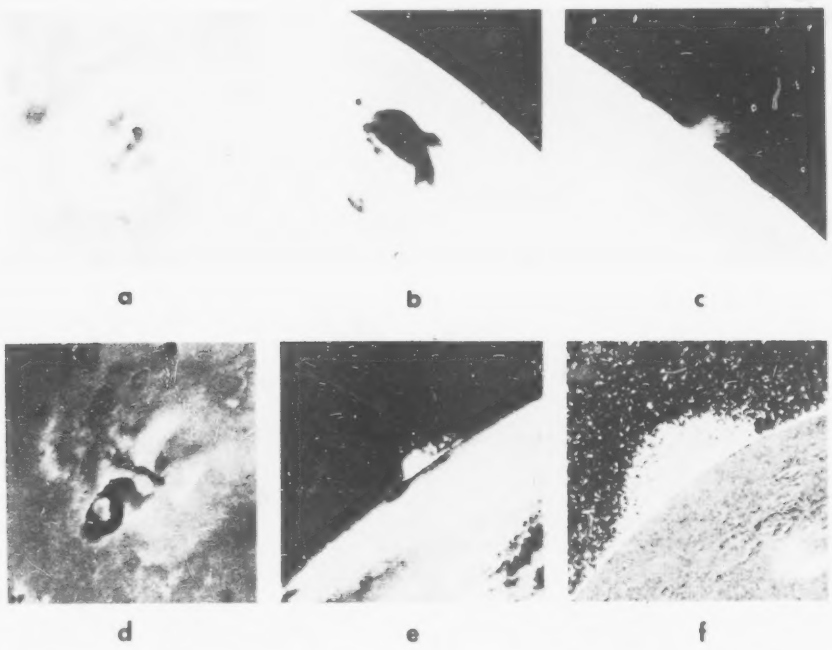

Photo credit: National Aeronautics and Space Administration

Successive images of volcanic plumes on Io, taken from the Voyager I spacecraft

some of these are no longer being formed; others are still being produced, by a combination of crustal movements and volcanic activity. Comparative studies of other terrestrial bodies are assisting in the resolution of these issues.

In many respects, Venus and Earth are twins, but they have taken radically different evolutionary paths. Scientists now think that Earth owes its particular course of development to the early formation of life. Life forms in the early ocean are thought to have pulled carbon dioxide out of the atmosphere and laid it down in limestone. Decreasing the level of carbon dioxide prevented the runaway greenhouse effect that characterizes the atmosphere of Venus, and this in turn preserved Earth's oceans. Recent evidence from Venus indicates that it once had oceans, too. Presumably, however, life did not appear at all there, or it did not become sufficiently widespread to remove much carbon dioxide.

The oceans are not a mere secondary feature of the Earth's surface; they permit continued evolution of its crust. Ocean water cools molten basalt emerging from the midocean ridges, thus making the basalt dense enough so that the continental plates can "float" above it. Without this oceanic cooling of basalt, the continents would freeze in place, as they have on Venus. In this view, sea floor spreading and plate tectonic motion, made possible by the presence of the oceans, provide

the present dynamic control of Earth's evolution. Thus, the presence of life and the presence of the oceans make Earth unique, at least in our star system. Life and the oceans each owes their preservation to the other, and the oceans control the way Earth's crust forms and therefore, indirectly, the course of evolution of living things. Without a study of Venus—an opposite case, where some particular differences have made all the difference—it is unlikely that our understanding of Earth's evolution would have progressed as far as it has.

Planetary science, therefore, has enlarged and deepened our understanding of the fundamental processes molding the Earth. In addition, it has given evidence both of what kinds of results might be expected if the balance of Earth's system were disturbed, and of how a relatively small change could drive the whole system into a dry, dead end.

FORMATION OF THE OZONE LAYER

The monitoring of ozone is one example of a practical activity growing out of space science. Ozone is a small, but important constituent of the Earth's atmosphere: too little of it in the stratosphere allows dangerous levels of ultraviolet radiation to reach the Earth's surface; too much of it near the Earth's surface has more immediate deleterious effects on human health. The level of ozone in the stratosphere can be altered both through increased technological activity, which causes relatively slow changes, and through alterations in the level of solar ultraviolet radiation, which causes more rapid fluctuations. Whereas increased technological activity tends to add compounds to the atmosphere which decrease the stratospheric ozone, solar ultraviolet radiation produces additional ozone. The mechanisms by which stratospheric ozone is formed and maintained are still not thoroughly understood, and space research systems are being used not only to monitor ozone but to measure related parameters which are critical to increasing our knowledge.

SOLAR PARTICLE EMISSIONS

Space research systems are also useful for measuring the level at which high-energy protons, emitted from solar flares, bombard the Earth's atmosphere, particularly at high latitudes. Instruments aboard spacecraft can detect the emission of these particles early enough so that the routes of aircraft flying over the polar caps may be changed or manned satellites may take appropriate precautions. To perform well, these warning systems must be sufficiently accurate to differentiate between flares that have a major effect and those that have only minor effects. The flare signatures that will provide this separation are not well defined, and only further basic research from space vehicles will provide the answers.

WEATHER AND CLIMATE

Another example of the practical effects of space science is the observation of the Earth's climate and weather. The Earth's weather and secular or cyclic changes in its climatic conditions have a significant impact on commercial activity. Accurate weather predictions are very useful for a variety of purposes, and accurate climatic forecasts could be of great strategic value—in predicting energy consumption requirements, for example. Accurate predictions depend on a substantial monitoring system in which satellites play a major role. If these satellites are to succeed in their missions, they must monitor the most predictive sets of parameters, and their downward-looking

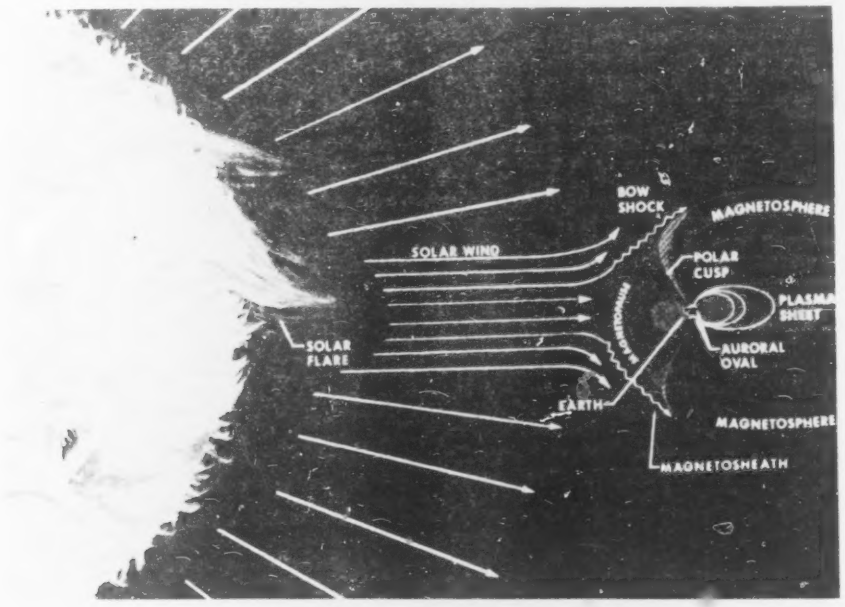

Photo credit: National Aeronautics and Space Administration

Sun-Earth radiation environment

systems must measure cloud cover, infrared and visible radiation, temperature, and the changes in these parameters. Because the relative reliability of these parameters is still under investigation, there is need for a continuing basic research partnership in which observations made from space and studies made from the ground are correlated, the parameters most critical over long time sequences are identified, and the largest available computers are employed—if there is a determination that the national interest is well served by more accurate weather predictions and climate monitoring.

Prediction of the Earth's weather presents an extremely complicated problem. Weather prediction is still in its infancy, and progress to date has been dependent on an increasingly sophisticated sensing system, combined with elaborate computer analysis. Space scientists are gaining further insight into how planetary atmospheres originate, circulate and evolve, principally because of recent space research on the atmospheres of other planets (Venus, Mars, Jupiter, and Saturn). This insight promises to remove some of the uncertainty in our knowledge of the circulation patterns of the Earth's atmosphere.

PROCESS INTERCHANGE IN THE EARTH'S ATMOSPHERE

Our life system on Earth is crucially dependent on a delicate balance and interchange of processes that occur at the interface of the Earth, the oceans, and the atmosphere. The presence of man and, in particular, the population explosion, compounded with the growth of industry, have begun to affect that balance in ways that are not yet understood. One primary means of monitoring and understanding these processes is through satellite remote sensing, an activity that is only a decade old.

Sampling the troposphere, the stratosphere, and much of the ionosphere can be done by Earth-based methods; the magnetosphere can be investigated only by space vehicles. The parameters of the "middle atmosphere," the region from 30 or 40 to 100 km above the Earth's surface, are still

uncertain, especially the composition and the electric fields of the region. If the effects that solar variations and the Van Allen Belt will have on spacecraft operating near the Earth are to be understood, the magnetosphere must be fully mapped throughout the solar cycle.

Landsat D—launched July 1982

EFFECTS OF SOLAR VARIATIONS ON COMMUNICATIONS

The Sun is the primary driving power underlying most processes on Earth, and its presence is an absolute necessity for our own existence. But the Sun is variable, and most of the variations that can occur have important effects on communications systems. Many of the important variations, however, can be seen only in regions of the spectrum accessible from above the Earth's atmosphere.

It had been known for decades that geomagnetic storms on the Earth seriously affect communications on the Earth, particularly at high latitudes. Geomagnetic storms result from streams of hot ionized gas that originate in solar storms, then are shot into interplanetary space, and finally impinge on the Earth's magnetosphere and disrupt communications. It is now known that the geomagnetic storms coincide with the arrival of streams of matter that travel much faster than the normal solar wind, and that these high-speed streams originate from regions on the Sun that do not emit X-rays, regions where there are "holes" in the low-energy X-ray emission, seen on photographs of the Sun taken in X-ray light. Thus, the presence of solar coronal holes, dark regions on an X-ray photograph of the solar disk, correlates significantly with geomagnetic storm activity on Earth.

Thus, there is a direct connection between the reliability of radio communications at high altitudes on Earth and our ability to monitor and study the Sun by X-ray satellites, by means of techniques not possible from the ground. The manifestations of this connection are not yet highly predictable, and the benefits of making them so will accrue only if basic research is continued.

SATELLITE RELIABILITY

Spacecraft operate in an environment that is largely foreign to us and virtually impossible to duplicate for study on the ground. In addition to the primary hazard of energetic particles in Earth's radiation belts, they are subject to differential charging, to emissions of electrons, protons, and other energetic particles from the Sun, to cosmic rays, and to high-energy solar and stellar ultraviolet, and X-ray and gamma ray radiation, any of which, if encountered in sufficient strength, can degrade the performance of the spacecraft. Damage may occur through irradiation of its detectors and electronics, electrostatic discharges, and the physical effects of collisions, including particle sputtering on mirror surfaces. As longer-lived satellites are orbited, degradation in performance because of environmental factors will be a more likely source of failure than will exhaustion of onboard energy sources.

The environment in which the now more than 4,000 manmade objects are orbiting the Earth is still not understood in detail. We do not yet know the time, frequency, or amplitude ranges over which variations in particulate bombardment and radiation take place. In the beginning of June 1980, for example, an unexpected increase in the flux of high-energy electrons at synchronous altitude particularly affected the performance of geostationary satellites. This result showed that the near-Earth space environment still held surprises and that instruments more immune to the effects of radiation had to be developed.

The requirement of the Department of Defense that the electronic components of its spacecraft be protected both against the natural radiation environment and, especially, against radiation from the explosion of nuclear devices has been the primary driver in the development of advanced "hardening" techniques. (The deep space probe Galileo, which must be able to withstand an environment of very high radiation around Jupiter, will be making use of some of these developments.) After these techniques are perfected, further study of the radiation environment around the Earth, particularly of the triggering mechanisms by which particles are dumped from the Earth's geomagnetic tail into the Earth's atmosphere, will be needed, if the national interest requires more assured satellite operations.

Common to civilian and military applications is the requirement to minimize payload weight while maximizing payload performance. This requirement has been the principal driving force behind the miniaturization of components, of which the development of tiny electronic circuits on silicon chips has been a major technological breakthrough. When these chips first found application on satellites, they were relatively large and not too densely packed. These features, combined with space hardening techniques, made the chips relatively reliable in the spacecraft environment. However, the technological state of the art in making chips has now progressed to the point where the chips are smaller and more densely packed, and have, size for size, orders of magnitude more capability than the previous generation of chips they will replace.

It is known that the new, high-density chips will be more susceptible to damage from radiation bombardment than were their predecessors, but it is not known how much more susceptible they will be. Here is another instance in which, if the answer is to be achieved, basic and applied research will both be needed: basic research to investigate the radiation environment, and applied research to investigate the effects of that environment on the new series of chips in order to predict how long they will last under various environmental conditions and under various degrees of radiation hardening.

COMMERCIAL IMPORTANCE OF NEAR-EARTH SPACE

The commercial importance of the space environment near the Earth has not yet been fully evaluated because, apart from the communications industry, there has been little involvement of the private sector. In the future, the investment of the private sector in space activities will almost certainly increase, particularly in satellite communications, remote sensing, and materials processing.

Materials processing in space (MPS) may be singled out as a new and interesting area for commercially oriented space research. In order to ease the way for industry to exploit the possibilities of MPS, NASA has developed the Joint Endeavor Agreement, in which the agency and industry share in the costs and the risks of the project: NASA provides technical advice and assumes the costs of the launch vehicle, including flight time, and industry provides the development funds.

One promising example of this Government-industry symbiosis is in drug manufacturing, where McDonnell Douglas Astronautics and the Ortho Pharmaceuticals Corp. of Johnson & Johnson are making a substantial investment in order to determine whether certain drugs can be manufactured in space more profitably than on the ground. Studies have shown that, by means of a process known as electrophoresis (a technique whereby a solution flows through an electric field in which molecules of different charges are separated from each other as a result of their migration in different directions at different speeds), it should be possible for cells to be separated from proteins about 100 to 400 times more quickly and with five times the product purity that can be obtained from the ground.

There are potential applications in the manufacture of interferon (a treatment for cancer), beta cells (a possible single-injection cure for diabetes), epidermal growth factor products (for treating burn patients), growth hormone products (for juvenile bone growth stimulation and the healing of ulcers), antitryspin products (for limiting the progress of emphysema), and antihemophilic products (for eliminating immunological reactions for hemophilia). In all these cases, there is promise that commercially viable quantities of these drugs can be made in the zero-gravity environment of space.

Materials processing is only one example of the possibilities of industrial use of near-Earth space. If these possibilities are to be exploited, scientists will require a better knowledge of the space parameters that may modify processes whose ground-based instances are well understood. If these developments are to be successful, continued interaction between pure space science and applied space science will be necessary.

Appendix A

Trends in the Space Science Budget

It is instructive to view the total NASA budget in the context of recommendations that were made within the administration in 1969, the year of the first Apollo landings on the Moon. Recognizing that the Nation needed to take a close look at the space program in the post-Apollo era, the President in February 1969 formed a Space Task Group (STG) to study the future course of the U.S. space program. STG was chaired by the Vice President, with membership from the Department of Defense (DOD), the National Aeronautics and Space Administration (NASA), and the office of President's Science Advisor.

The report, entitled "The Post-Apollo Space Program: Directions for the Future," was received in September 1969. It presented a comprehensive plan which presented three possible program levels to achieve five program objectives: 1) increased emphasis on activities that have service to man (an expanded space applications program); 2) an enhanced defense posture for the Nation; 3) continuation of a strong program of space research to increase man's knowledge of the universe; 4) development of new systems and technology for space operations, emphasizing certain critical factors as: a) commonality, b) reusability, and c) economy, through the development of a new space transportation capability and space station modules; and 5) promotion of programs that provide broad international participation and cooperation.

The three program levels all contained a space shuttle, a 12-man space station, a 100-man space base, and lunar orbiting and surface stations. Two of the three options also included a manned mission to Mars. The time frames of these options differed, depending on the annual budgets projected for the future, which varied from $6 billion to $10 billion per year (1969 dollars). Figure A-1 shows a comparison of those NASA funding options (I, II and III, with a low-level bound having no manned flight). The upper curve marked "maximum pace bound" presents the funding required for a program limited not by funds, but by technology; the low-level program was constructed with an increased unmanned science and applications effort without a manned flight program. Figure A-1 also shows in 1969 dollars what level of funding for NASA actually was achieved.

In the post-Apollo era there was opposition to the levels of the space program proposed in the STG report which was expressed by critics in Congress, in the media, and in the American public generally and which led to a stretched-out time schedule shown in figure A-1. The actual program included the development of the space shuttle, but the rest of the recommendations of STG were not implemented. At the moment, no effort to develop a space station has been approved by the administration, despite the fact that the Soviet Union has been very active in developing a strong capability in this field for a number of years and will soon be able to sustain a permanent presence of man in orbit, either around the Earth or around the Moon.

Figures A-2 and A-3 show the space science budget of the NASA Office of Space Science and Applications (OSSA) from fiscal year 1964 to fiscal year 1983, expressed in millions of (1983) dollars, corrected for inflation.[1]

They are expressed in numerical form in tables A-1 and A-2. Three major components of the space science budget are shown: 1) the planetary sciences program, 2) the physics and astronomy program, and 3) the life sciences program. The factors by which actual budget figures have been converted to constant dollar figures are given in the middle (escalation) columns in table A-1. Table A-2 shows the budgets for individual flight programs during the same time interval, expressed in current-year dollars.

Several features of figures A-2 and A-3 deserve mention. First, in terms of purchasing power, the *total* budget for space science from the mid-1960's to the present time has fallen from about $1,450 million to about $650 million, or to approximately 45 percent of its former size. Most of this decline took place precipitously between 1966 and 1969. The budget increased again, but by only 50 percent of its decline, from 1972 to 1975, but fell again to its current value of about $650 million by 1977.

Reference to the other components of figure A-2 shows the trends of those components during the same time interval. The physics and astronomy program decreased by approximately 50 percent in the decade from 1964 to 1974, but has regained about two-thirds of its former value since 1974, principally because of increased funding for Space Telescope. The planetary science program was cut to one-third of its 1965 level by 1969, but grew to slightly more than its 1965 level by 1972-74, principally because of funding support for the Mars Viking program and the beginning of the

[1]The budget figures for the NASA Office of Space Science and Applications were supplied to OTA by I. Duke Stanford (NASA/OSSA).

Figure A-1.—Annual NASA Expenditure and Options

Voyager programs. However, as these programs tapered off, starting in 1974 and 1976, respectively, the budget for planetary sciences underwent a sharp decrease from its peak of $900 million (1983 dollars) to its current level of about $200 million, a drop to 22 percent of its value in 1974. The life sciences component of the NASA space science budget has remained relatively constant for the past decade.

Reference to figure A-3 shows that the life sciences have typically taken about 510 percent of the space sciences budget for the past two decades. The budget for planetary science exceeded the budget for physics and astronomy from 1964 to 1968 and from 1970 to 1976, whereas the budget for physics and astronomy exceeded the budget for planetary science for 1969 and for the period from 1977 to the present. The budget for planetary science has been significantly lower in 1981-1983. It was noted that the fiscal year 1983 budget is still under discussion at the time of this writing (August 1982).

Appendix D

Shuttle/ELV Price Comparison

The estimated price to place a 2,750 lb spacecraft into geosynchronous transfer orbit if launched in 1982 is as follows:

	Shuttle (in millions)	Delta (in millions)
Transportation	$ 8	$ 30
Upper stage	4-5	3-4
Total estimate*	$12-13	$33-34

The above shuttle price is derived using the shuttle introductory period price of $18 million (in fiscal year 1975 economics) for a dedicated shuttle launch during the 1982-85 timeframe. If the recently established $38 million price (in fiscal year 1975 economics) for a 1986-87 launch is used, the equivalent price for a 1982 launch would be:

	Shuttle (in millions)	Delta (in millions)
Transportation	$ 17	$ 30
Upper stage	4-5	3-4
Total estimate*	$21-22	$33-34

*Costs include payload integration.

Appendix E

Economics of the Space Shuttle

by James A. Van Allen

In April 1982, James A. Van Allen of the University of Iowa presented to a meeting of Tau Beta Pi a paper entitled "Applications of Space Research to Modern Day Society." In preparation for the May 5 OTA workshop in which he participated, Van Allen sent a copy of that paper to OTA. Included here is the section of that paper in which he treats the economics of the space shuttle. Van Allen's analysis, which differs markedly from NASA's, is included in order to show how the space shuttle may have, more or less directly, affected the funding for space science. It is included with only minor explanatory comments. The reader should note that Van Allen includes overhead costs* in his calculations; these costs are not included when calculating marginal costs.[1]

The opinions expressed by Van Allen are his own and do not necessarily reflect those of OTA.

> There were many . . . weaknessess in the famous forecast of $100 per pound into orbit . . . I have prepared several (charts) analyzing the economics of the shuttle. The summary of this analysis is that there is no prospect whatever of bringing shuttle launch costs below some $5,000 per pound (1982 dollars). Even this figure is optimistic because my assumed payload of 60,000 lb per flight includes the mass of upper stages and other equipment that is not properly classified as useful payload.
>
> Hence, for realistic missions during the next 20 years or so, the shuttle system is actually much more expensive than are conventional, expendable boosters as exemplified by Delta, the Atlas-Centaur, the Titan-Centaur, and the French-German Ariane, all of which are in the advanced state of development and available for frequent use.

*Overhead costs are defined to be the fixed costs of the Federal establishment and associated contractors for maintaining the full operational capability of conducting a program of space shuttle flights, whether or not such flights actually occur.

[1]See, for example, Engel, Rolf, 1982, *Interavia* vol. 2, No. 177.

Table E-1A.—Shuttle Economics (Federal Government)

N = Number of flights per year
O = Annual overhead
A = Out-of-pocket costs per flight
P = Cost per payload
M = Mass of payload
C = Cost per flight
L = Launch cost per pound of payload

$$C = \frac{O + N(A + P)}{N}$$

$$L = \frac{O + NA}{NM}$$

OTA's comments: Table E-1A gives Van Allen's basic equation in which the quantity C, the cost per flight, is expressed as a function of overhead costs, the number of flights per year, the out-of-pocket costs per flight, and the cost per payload.

Table E-1B.—Shuttle Economics (Federal Government)

Examples:
O = $2,000,000,000 per year
A = $40,000,000 per flight
P = $100,000,000 per payload
M = 60,000 lb

N	Annual total	C	Launch cost per lb of payload
1	$2,140,000,000	$2,140,000,000	$34,000
3	2,420,000,000	806,700,000	11,780
10	3,400,000,000	340,000,000	4,000
50	9,000,000,000	180,000,000	1,300

OTA's comments: Table E-1B uses Van Allen's basic formulas of table E-1A to compute values of launch cost per pound of payload as a function of the number of flights per year N for assumed values of O, A, P, and M as listed at the head of table E-1B.

Van Allen's comments: This analysis ignores overhead during the 10-year developmental period: amortization of the investment for development of the vehicle and for facilities; and interest on the investment during the developmental and amortization periods.

Note that often quoted "marginal" or incremental launch cost per flight is the quantity A, a grossly unrealistic representation of the true cost. For the examples given here the "marginal" launch cost per pound of payload is $670, irrespective of the number of flights per year.

Note: "Payload" includes upper stages, if they are necessary, plus other equipment not properly considered useful payload.

Table E-2A.—Shuttle Economics
(Private enterprise/Federal Government)

Van Allen's comments:
Assumed: That the Space Transportation System including facilities had been developed by private enterprise and then had been taken over by the Federal Government.
I = direct investment costs accrued linearly as a loan over a period of 10 years
The direct investment costs plus interest over the developmental period are then amortized linearly over an operational period of Y years by the Federal Government.
X = annual interest rate over (10 + Y) years
In this case the *additional* annual cost averaged over the Y years of operational use is given by
$Z = (I + 51X) (1/Y + X/2)$
Numerical examples are given in table E-2B for N = 1, 3, 10, and 50 launches per year.

Table E-2B.—Shuttle Economics
(Private enterprise/Federal Government)

Examples:
I = $15,000,000,000
Y = 15 years
X = 0.1 (10%)
Z = $2,625,000,000

N	Annual total	C	Launch cost per lb of payload
1	$4,765,000,000	$4,765,000,000	$77,750
3	5,045,000,000	1,681,700,000	26,360
10	6,025,000,000	602,500,000	8,380
50	11,625,000,000	232,500,000	2,270

Van Allen's comments: "Payload" includes upper stages, if they are necessary, plus other equipment not properly considered useful payload.
Assumed values of O, A, P, and M are the same as in table E-1B.
All estimated cost figures in tables E-1A, 1B, 2A, and 2B are given in 1982 dollars.

OTA's comments: Table E-2B uses the formula of table E-2A to calculate four specific examples of the launch cost per pound of payload. Taking a developmental cost of $15 billion amortized over 15 years at an interest rate of 10 percent, Van Allen calculates that for 1, 3, 10, or 50 flights per year, the total (*not* marginal) launch cost per pound of payload will be $77,750, $26,360, $8,380, or $2,270, respectively.
Van Allen's calculations are intended to call into question the assertion that the shuttle will be able to bring the launch cost per pound of payload down to $100 to $300/lb. It should be noted, however, that this figure is the *marginal* launch cost per pound of payload, and that Van Allen's calculations are based on the *total* launch cost per pound of payload. It is, of course, the *total* cost of the shuttle which has had an impact on the space program.

INTRODUCTION

In the 1958 law establishing the National Aeronautics and Space Administration, Congress charged NASA with conducting its research activities "so as to contribute ... to the expansion of human knowledge of phenomena in the atmosphere and space." Recognizing that such knowledge, like much of the knowledge generated by research, could also have potential applicability in non-aerospace sectors of the economy, Congress further directed NASA to "provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

NASA's success in accomplishing its aerospace objectives is unquestioned. The achievements of the satellite programs, manned space flights, and exploration of the moon are dramatic and well-known. Less clear, however, is the extent to which the knowledge developed in the NASA programs has been useful outside its originally intended aeronautical and space applications. While literally hundreds of instances of non-aerospace applications, ranging from the cardiac pacemaker to gas turbines, have been cataloged, hardly anything is known of the quantitative economic significance of NASA's contributions.

The purpose of this study was to develop preliminary estimates of the economic benefits to the U.S. economy from secondary applications of "NASA technology." If technology is defined as the body of knowledge

concerning how society's resources can be combined to yield economic goods and services, then NASA technology represents NASA's contribution to this body of technical knowledge. Secondary applications refer to uses of NASA generated knowledge for purposes other than those primary mission-oriented ones for which the original R&D was done. These applications occur whenever a non-NASA entity, with or without encouragement from NASA, uses this knowledge in some economic activity.

B. MEASUREMENT APPROACH

The development of procedures to quantify the economic benefits of secondary applications involved the adoption of concepts and tools that are theoretically sound and yet practically useful in dealing with a wide variety of applications of NASA technology. There are two key foundational elements of the approach: one, an understanding of how technological change generates economic benefits; and two, a determination of the role that NASA can play in the process of technological change.

1. The Economic Benefits of Technological Change

In broad terms, the economic process involves the conversion of society's stock of resources into goods and services and the sale or exchange of these goods and services in the marketplace. This activity generates economic benefits by allowing people to consume desired combinations of goods and services. Advancing technology increases these benefits by allowing society to get more from the same stock of resources.

The specific methods for quantifying economic benefits have been the subject of much discussion in the economics literature. The most widely accepted principle for evaluating economic benefits is founded on individuals' "willingness to pay" to move from a "less" to a "more" preferred state. What this principle translates into for the purposes here is that the benefits of technological change can be measured as the cost savings generated by new or improved production processes plus the extra value that consumers attach to new or improved final products. Therefore, by determining how cost and demand for various products are affected by specific technological advances, one can estimate the benefits of these advances.

2. The Benefits Due to NASA

The research process by which technological advances are generated typically involves a complex interaction of various groups and individuals. In solving the particular problems associated with an advance, the individual research "actors" build on or combine their results with those generated by others. As a result, any "credit" for the benefits created by a particular advance should, in a real sense, be shared by the various contributors.

The goal here, of course, is to assign a particular share to NASA in some specific cases. The method for assigning this share is based on the premise that NASA R&D led to an earlier realization

of the particular technological advances being considered. In other words, had NASA not done its R&D -- and had its failure to do so not led to changes in R&D by others -- these technological advances would indeed have occurred, but at a later date.

If one accepts this view of technological advance -- and it has been proposed and defended by a number of authors -- then the measurement of benefits attributable to NASA becomes, at least theoretically, a rather straightforward task. These benefits can be measured as the difference between the present value of two benefits streams: one, the stream resulting from the advance as it has occurred, and two, the stream that would have resulted had NASA not been involved.

In each of the specific cases technical experts outside the NASA establishment were questioned about the speed-up resulting from NASA's role. Of course, there was some variation in their judgment. In order to allow for the inherent uncertainty in this aspect of the study, calculations were made based on alternative assumptions concerning the extent to which NASA accelerated the time stream of benefits. More specifically, benefits were calculated based on a minimum, a maximum, and a conservative "probable" speed-up due to NASA.

C. RESULTS OF CASE STUDIES

Before describing the results of the analysis, three points are worthy of mention. First, the case studies are by no means

38-036 O - 84 - 20

a random selection from the possible cases which might have been examined. Cases were deliberately selected where data were available, where NASA's role was widely acknowledged, and where benefits were anticipated to be relatively large. Consequently, until additional experience with more case studies is acquired, it is not possible to draw inferences regarding the total secondary benefits of NASA's R&D. Second, because the case selection was not random and because of the innovative nature of the work, an effort was made to be conservative in the calculations. Third, the brief discussion of the cases which follows is not sufficient for a full understanding of the qualifications and limitations of the analyses. To acquire a more complete comprehension of these, a careful reading of the technical report is required.

1. Cryogenic Multilayer Insulation Materials

NASA's role in cryogenic technology is an outgrowth of the effort to minimize the weight, volume, and evaporative loss of gases used in launch and flight propulsion systems, life support systems, and power generation on board spacecraft. An integral part of this general concern was the design of improved insulation systems. The development of cryogenic insulation technology has contributed substantially to the rapid growth of the cryogenics industry.

In this case study, benefits are calculated as the cost savings generated by the use of multilayer insulation instead of the next best

insulation material (perlite) in the transport of liquid hydrogen, liquid helium, and liquid nitrogen. It should be emphasized that other savings arise from the use of multilayer insulation with liquid hydrogen, helium, and nitrogen, insofar as it is used to insulate storage tanks, piping and other equipment used in the production of these liquid gases.

The two principal sources of measured cost savings due to multilayer insulation are: reduced boil-off loss during the time the cryogen is transported, and reduced transportation costs due to the lighter weight of multilayer insulated tanks. Benefits were estimated using an engineering approach to specify the relevant technical relationships between evaporation loss, weight, and insulation characteristics. The "best guess" or "probable" estimate of benefits is $1,054 million.

2. Integrated Circuits

Prior to 1960, conventional electronic circuitry was based on the assembly of individually-encapsulated circuit components such as transistors, resistors, capacitors, and diodes. Integrated circuit technology -- the combination of these circuit functions on an inseparable, continuous base--provides significant advantages over conventional circuit technology, particularly in smaller size, lower power consumption, increased speed of operation, improved reliability, and reduced cost per electronic function. These features make integrated circuits especially attractive for space applications.

The introduction of integrated circuit technology produced significant changes in all electronic products, including consumer electronic products, and the estimates of the total benefits to advancing integrated circuit technology reflect its very widespread applicability.

Based on a simultaneous equation estimation of the demand for integrated circuits, estimates of benefits were derived. The "probable" estimate is $5,080 million.

3. Gas Turbines in Electric Power Generation

Since the early 1940's NASA (then NACA) has been intimately involved in gas turbine technology, primarily as it relates to improvement of jet engines for military and commercial aircraft. This basic research has also produced benefits in the production of electric power, as gas turbines have become more widely used as sources of peaking power and standby capacity.

The use of gas turbines in electric power generation undoubtedly confers may social benefits; e.g., gas turbines are relatively "clean" from an environmental point of view and also enhance the reliability of power production. Nevertheless, the estimates of benefits are based only on the fuel cost savings in power production produced by improvements in gas turbine performance. Improvements in gas turbine performance are assumed to result from advances in turbine technology; gas turbine vintage was used as a proxy for technology level in these calculations. Using standard regression analysis, the relationship between gas turbine vintage and the average cost of fuel consumed in the production of power was estimated; based on this relationship, a "probable" estimate of the total fuel cost savings of $111 million was determined.

4. NASTRAN

NASTRAN (NASA Structural Analysis) is a general purpose finite element computer software package for static and dynamic analysis of the behavior of elastic structures. Industrial users are generally product engineers in mechanical or civil engineering applications such as aircraft and automobile production, bridge construction, or power plant modeling.

NASA's Goddard Space Flight Center developed NASTRAN, through a combination of in-house and contracted research, over the period 1965 to 1970. It represented substantial improvement over similar extant programs, and was released to public users in November of 1970.

Because few published data exist regarding the extent of use of NASTRAN, estimates of cost savings from the use of NASTRAN were obtained from telephone interviews with a sample of users. From the sample responses the "probable" benefits accruing to the population of NASTRAN users were estimated at $701 million.

D. SUMMARY AND CONCLUSIONS

A summary of the "probable" estimates for each case study is presented in Table 1. It indicates that total benefits due to NASA for the four cases studied are probably on the order of $7,000 million.

Table 1

Results of Benefits Estimation

Technology	Interval of Benefits Estimation	Estimated Probable NASA Acceleration (Years)	Probable Benefits Attributable to NASA (Millions)
Gas Turbines	1969 - 1982	1.0	$ 111
Cryogenics	1960 - 1983	5.0	$1,054
Integrated Circuits	1963 - 1982	2.0	$5,080
NASTRAN	1971 - 1984	4.0	$ 701
Total	—	—	$6,946

In interpreting the results of this study one should recognize that it is one of the first of its kind ever attempted. The results, while arrived at through careful and rigorous techniques, are sensitive to data uncertainties and analytical simplifications. Though one must necessarily view such results with caution, it seems that the following general observations could be safely made:

- Operational methods can be developed for estimating the secondary benefits of mission oriented R&D.
- Secondary benefits attributable to NASA's R & D programs may be impressively large. For example, the $7,000 million total for the four cases studied is more than twice NASA's present yearly budget.
- Because secondary benefits may indeed be significant, public decisions concerning the allocation of resources to research and development programs should, where possible, consider such benefits.

FINAL REPORT

THE ECONOMIC IMPACT OF NASA R & D SPENDING
EXECUTIVE SUMMARY

Chase Econometrics

Abstract

In this study Chase Econometrics, Inc., has undertaken an evaluation of the economic impact of NASA R & D programs. The crux of the methodology and hence the results revolve around the interrelationships existing between the demand and supply effects of increased R & D spending, in particular, NASA R & D spending. The demand effects are primarily short-run in nature and have consequences similar to that of other types of government spending. The supply effects, which represent the results of a higher rate of technological growth manifested through a larger total productive capacity, are long-run in nature and have consequences very dissimilar to that of general types of government spending.

The study is divided into two principal parts. In the first part, the INFORUM Inter-Industry Forecasting Model is used to measure the short-run economic impact of alternative levels of NASA expenditures for 1975. The principal results of this part of the study are that a shift toward higher NASA spending within the framework of a constant level of total Federal expenditures would increase output and employment and would probably reduce the inflationary pressures existing in the economy. Hence, Chase concludes that NASA spending is more stabilizing in a recovery period than general government spending.

In the second part of the study, an aggregate production function approach is used to develop the data series necessary to measure the impact of NASA R & D spending, and other determinants of technological progress, on the rate of growth in productivity of the U. S. economy. The principal finding of this part of the study is that the historical rate of return from NASA R & D spending is 43 percent.

Chase Econometrics

In the final part of the study, the measured relationship between NASA R & D spending and technological progress is simulated in the Chase Macro-econometric Model to measure the immediate, intermediate, and long-run economic impact of increased NASA R & D spending over a sustained period. The principal findings of this part of the study are that a sustained increase in NASA spending of $1 billion (1958 dollars) for the 1975-1984 period would have the following effects:

1) Constant-dollar GNP would be $23 billion higher by 1984, a 2% increase over the "baseline," or no-additional-expenditure projections.

2) The rate of increase in the Consumer Price Index would be reduced to the extent that by 1984 it would be a full 2% lower than indicated in the baseline projection.

3) The unemployment rate would be reduced by 0.4% by 1984, and the size of the labor force would be increased through greater job opportunities so that the total number of jobs would increase by an additional 0.8 million.

4) By 1984 productivity in the private non-farm sector would be 2.0% higher than indicated in the baseline projection.

Other simulations, of $100 to $500 million increases, show proportional results.

The large beneficial economic effects of NASA R & D programs, particularly the unique combination of increased real GNP and a lower inflation rate, stem from the growth in general productivity resulting from NASA programs. Growth in productivity means that less labor (and/or capital) is needed per unit of output. This results in lower unit labor costs and hence lower prices. A

Chase Econometrics

slower rate of inflation leads in turn to a more rapid rise in real disposable income, which provides consumers with the additional purchasing power to buy the additional goods and services made possible by the expansion of the economy's production possibility frontier. Finally, the increase in real consumer expenditure leads to an increase in demand for the services of labor.

Chase Econometrics

Introduction

Chase Econometric Associates, Inc. has undertaken an evaluation of the economic impact of NASA R & D spending on the U. S. economy. This study reports on both the short-run and long-run effects of changing levels of spending. Both the Chase Econometrics macro model and input-output model are used to calculate the impact of different spending levels on the overall economy and on specific industries in the short-run part of the study. The long-run part of the study includes an estimate of the relationship between NASA R & D spending and the rate of technological growth. This relationship is used to determine how much higher spending levels would raise aggregate supply and increase the total productive capacity of the economy. The demand effects stemming from an increase in spending are not substantially different from traditional multiplier analysis and are primarily short-run in nature. The supply effects do not begin to have a significant effect on aggregate economic activity until five years later, but the ultimate effects are much larger and very different than the effects of most forms of government spending.

Short-Run Impacts of NASA R & D Spending

Description of Approach

The first part of the study deals with the short-term economic impact of NASA expenditures and attempts to answer the question of whether a higher level of NASA expenditures is more beneficial to the U. S. economy than a lower level during the year that the expenditures are made, holding the level of total

Chase Econometrics

Federal spending constant. This analysis is useful in examining the effects of altering the level of NASA expenditures as part of an overall economic stabilization policy.

The economic impact was calculated by preparing two forecasts of the U. S. economy for 1975 using alternative levels of NASA expenditures, which we term NASAHI and NASALO. The NASALO forecast assumed an expenditure by NASA of $1.35 billion in 1971 dollars for goods and services (excluding NASA employee wages) during calendar 1975. The NASAHI forecast assumed an expenditure of $2.35 billion by NASA with other Federal government spending reduced by $1 billion, hence leaving the total level of government spending unchanged. Because of this, the aggregate economic impact shown for this shift is quite small.

In order to measure the differential industry effect of the NASAHI and NASALO expenditure levels, we utilized the INFORUM Inter-Industry Forecasting Model. This model, which was developed by the Interindustry Forecasting Project of the University of Maryland, has been expanded and modified by Chase Econometrics and has been linked to the Chase Econometrics Macroeconomic Forecasting Model to provide consistent economic forecasts for the industries included in the model. Through use of this model, it is possible to forecast the impacts on major economic indicators such as inflation, employment, GNP, and productivity of a shift in the Federal budget to a higher level of NASA spending.

Short-Run Results

The effects of the two alternative forecasts on the aggregate economy, as estimated through use of INFORUM, are shown in Tables 1 and 2. While the results are not dramatic, they do indicate that the direction of change in economic activity from an increase in the level of NASA expenditure is positive

Chase Econometrics

TABLE 1

MACROECONOMIC IMPACT OF NASAHI AND NASALO EXPENDITURES

	NASALO 1975	NASAHI 1975
Gross National Product	1529.9	1530.1
Gross National Product (1958$)	820.7	820.7
Consumer Price Index (% change)	10.5	10.5
Disposable Personal Income	1084.9	1085.0
Federal Government Deficit	17.0	16.9

All figures are in billions of dollars except where indicated otherwise.
NASAHI = NASA expenditures during 1975 of $2.35 billion in 1971 dollars.
NASALO = NASA expenditures during 1975 of $1.35 billion in 1971 dollars.

TABLE 2

EMPLOYMENT BY INDUSTRIES AFFECTED BY A NASA SPENDING SHIFT

	Total				- 7
	Net gain in Manufacturing Employment (thousands of jobs)				+20

Chase Econometrics

and beneficial. The magnitudes are small because the total Federal expenditure has not been altered and these improvements result solely from a shift within total Federal expenditures. Nonetheless, these results do indicate that NASA expenditures are less inflationary than other Federal government expenditures, and that a shift toward higher NASA spending with a constant Federal expenditure is not inflationary in the present economy. Conversely, it would follow that a shift away from NASA to other Federal programs could be relatively inflationary in the present economy. Further, the employment effect of NASA expenditures is beneficial, although not large for this small change, and thus both goals of higher employment and lower rates of inflation would be hindered by a lower level of NASA expenditure.

Thus in this section of the study we show that a shift to NASA expenditures from other Federal government spending will stimulate the economy without raising prices. In particular, we found the following effects of a shift of $1 billion in 1971 dollars.

1) A higher level of NASA expenditures would not have had an inflationary impact on the U. S. economy during 1975 and would probably have reduced the inflation pressures in the economy.

2) A shift of $1.0 billion in 1971 dollars, or $1.4 billion in 1975 estimated prices, from other Federal non-defense expenditures to NASA expenditures would have reduced the inflationary pressures in several key basic materials industries.

3) A shift to increase NASA expenditures would have increased employment by 25,000 in the missile and ordnance and aircraft industries. While it would have reduced employment in ten other industries, the net increase in the manufacturing sector would have been 20,000 jobs.

Chase Econometrics

4) Output would have been stimulated in twenty-one industries. The principal industries which would have been affected had considerable excess capacity in 1975 and were producing at levels well below their peak years and in most cases below the average of the past five years.

The general conclusion reached in this section is that a shift toward higher NASA spending within the framework of a constant level of total Federal expenditures creates jobs without raising the rate of inflation, and hence is more stabilizing in a recovery period than general government spending.

The Impact of NASA R & D on the Rate of Change of Technological Progress

Description of Approach

The second part of this study is an examination of the historical relationship between NASA R & D spending and the rate of technological progress. This examination requires two steps: (1) the construction of a time series to measure the rate of change of technological progress; and (2) an empirical investigation through regression analysis of the determinants of technological progress suggested by economic theory.

(1) Time Series for γ (gamma). The time series representing the rate of change in technological progress (γ) is a somewhat elusive measure, inasmuch as it requires developing a series for potential Gross National Product (GNP) as well as related series for labor and capital inputs. The series that was developed to measure γ is based on the methodology used by the Council of

Chase Econometrics

Economic Advisers. In addition, an alternative series for γ was developed, following the methodology of E. F. Denison, to test the sensitivity of the results to a change in the formulation of the γ series.

Our formulation of γ is as follows:

$$\gamma = \frac{\Delta X}{X} - \alpha \frac{\Delta L}{L} - (1 - \alpha) \frac{\Delta K}{K}$$

where X = full capacity or maximum potential output (national income or GNP) in constant prices

L = maximum available labor force

K = capital stock, defined as $K = \sum_{i=0}^{N} \lambda^i I_{t-1}$ where λ is the rate of economic depreciation and I is fixed nonresidential investment.

α = share of potential output

γ = the rate of technological progress (that is, the rate of increase in full capacity real GNP that cannot be accounted for by a change in either the size and composition of the labor force or the size and composition of the capital stock).

(2) Determinants of γ. Economic theory and prior econometric studies suggest the following possible determinants for γ: (a) R & D spending; (b) an industry mix variable; (c) an index of capacity utilization; (d) an index of labor quality reflecting changes in age mix, sex mix, health levels, and educational levels of the labor force; and (e) an index of economies of scale. After considerable experimentation, we found the latter two determinants to be insignificant for the time period examined. The exclusion of economies of scale as an explanatory variable for γ can be justified on theoretical grounds since this variable is generally relevant to only firm

Chase Econometrics

or industry or underdeveloped nation studies. The statistical insignificance of the labor quality variable may be partly explained by the fact that some of its characteristics are already reflected by the manner in which we constructed the labor force variable used to generate γ. Undoubtedly, the insignificance of the labor quality variable is also partly due to our inability to reflect significant improvements (variability) in labor education and training over an observation period as short as 15 years.

Hence, based upon both theoretical considerations and empirical investigation, we offer the following conclusions regarding the determinants of γ. First, R & D spending should be included as a determinant and should be subdivided into two explanatory variables, namely, NASA R & D spending and other R & D spending. Secondly, we found that both R & D variables could be closely approximated by a distributed lag structure that follows the general shape of an inverted U-distribution; that is, as a result of an increase in R & D spending in year 0, modest increases in the productivity growth rate begin in year 2, peak in year 5, and terminate in year 8. The actual distributed lag weights, determined by the Almon method and used in the study, are given in Table 3. Thirdly, an industry mix variable should also be used in the equation that attempts to explain movements in γ. This specification is necessary to capture the impact on γ of shifts over time in resource allocation from high- to low-technology industries. Finally, the equation expalining γ should also include a capacity utilization variable to account for the fact that shortages and bottlenecks reduce productivity growth as the economy approaches full capacity.

Chase Econometrics

The Measured Effect of R & D Spending on Productivity Growth

(1) The Regression Equation. The final regression equation which was used to explain γ in this study is as follows:

$$\gamma = -1.81 + \underset{(3.9)}{0.426} \sum_{i=0}^{7} A_i \, (NRD)_{-i} + \underset{(2.0)}{0.074} \sum_{i=0}^{7} A_i \, (ORD)_{-i} \, \frac{(1-Cp)}{(1-\overline{Cp})}$$

$$+ \underset{(4.5)}{0.031} \, (IM - \overline{IM}) - \underset{(3.1)}{0.157} \, (Cp - \overline{Cp})$$

$\bar{R}^2 = 0.883$
DW = 1.95
Sample Period 1960-1974

where: NRD = NASA R & D spending as a proportion of GNP

ORD = other R & D spending as a proportion of GNP

IM = industry mix variable, fraction

Cp = index of capacity utilization, percent

Chase Econometrics

The numbers in parentheses below the regression coefficients represent t-statistics. As can be seen from the regression results, all coefficients are statistically significant and the overall fit of the equation to the data, as measured by the $\bar{R}^2$ value of 88.3 percent, is impressively high, especially for a first difference equation.

(2) The NASA Contribution to γ. Using the regression results above, we found that the increased levels of constant-dollar GNP stemming from a $1 billion increase in constant-dollar NASA R & D spending in 1975 are as given in Table 4. For purposes of this calculation we hold the baseline level of GNP constant and ignore all interactive and dynamic demand and supply multipliers. As will be explained later, the actual changes in GNP will be considerably larger once we do include the effect of these multipliers.

TABLE 4

INCREASE IN GNP PER UNIT INCREASE IN NASA R & D SPENDING
"PURE" PRODUCTIVITY EFFECTS ONLY

Year	Cumulative Change in GNP
1975	0
1976	0
1977	0
1978	0
1979	0.26
1980	0.96
1981	1.90
1982	2.88
1983	3.74
1984 and succeeding years	4.26

Chase Econometrics

The rate of return on NASA spending may be found by substituting the results of Table 4 into the conventional rate of return formula. For a $1 increase in spending, the appropriate expression would be

$$\frac{0.255}{(1+r)^5} + \frac{0.952}{(1+r)^6} + \frac{1.888}{(1+r)^7} + \frac{2.882}{(1+r)^8} + \frac{3.736}{(1+r)^9} + 4.261 \left[\frac{\left(\frac{1}{1+r}\right)^{10}}{1 - \frac{1}{1+r}} \right] = 1.00$$

where r is the rate of return. Solving this equation yields r = 43% to the nearest percent. If we re-solve the equation by substituting $\frac{4.26}{(1+r)^{10}}$ for the last term, thus not assuming an infinite life, we find the rate of return diminishes to 38%.

Thus an increase of $1 billion in NASA R & D spending would increase productivity and total capacity of the U. S. economy by $4.26 billion in 1984 and each succeeding year. It should be stressed that this figure stems from a $1 billion increase in 1975 and then a return to previous spending levels. If spending were to remain $1 billion higher indefinitely, the first-order supply effects, i.e., disregarding interactive and dynamic effects, are shown in Table 5. As indicated above, the actual results are significantly larger because of the demand and multiplier effects calculated by simulating the Chase macroeconomic model.

Chase Econometrics

Macroeconomic Impacts of NASA R & D-Induced Technological Progress

The third part of the study uses the relationship which has been developed between NASA R & D spending and the rate of technological progress to translate an increase in spending into a higher overall level of productivity for the U. S. economy. This section features a number of simulations with the Chase Econometrics macro model which determine the total effect of higher NASA R & D spending on the economy when interactive and dynamic effects are taken into account. These simulations consider the supply side of the economy as well as the demand side, and stress the fact that real GNP can be expanded by increasing productivity and lowering prices as well as by increasing government spending.

Chase Econometrics

Approach to Determining Macroeconomic Effects

Up to this point we have considered only the static supply or "pure" productivity effects of NASA R & D spending. We now employ the Chase Econometrics macro model to determine the effects of an increase of $1 billion in constant prices (1958 dollars) in NASA R & D spending. We assume that such spending is increased by this amount at the beginning of 1975 and remains in force throughout the next decade. There are two types of effects from this increased spending.

The first type of effect is the ordinary expenditure (demand) impact of increased government spending. The second type of effect--this effect being what really differentiates NASA R & D from other types of government spending--is the longer run impact of NASA R & D-induced changes in the rate of technological progress. These changes lead to an expansion in the productive capacity of the economy and ultimately lead to an increase in society's standard of living.

(1) The Expenditure (Demand) Impact of NASA R & D. In a period of economic slackness, an increase in government spending leads to increased real GNP and lower unemployment. These expenditure effects for NASA R & D are not markedly different than those experienced for most increases in other types of government spending or for the release of funds to the private sector for construction. It should be noted, however, that NASA R & D expenditure increases have a larger impact per dollar than similar spending on welfare or low productivity type job programs.

Chase Econometrics

(2) The Important Productivity Impacts of NASA R & D. The productivity impacts of NASA R & D generate social benefits in a somewhat more complex manner. We have already shown above (Table 5) the magnitude of increase which will occur in the productive capacity of the economy for an increase in NASA R & D spending. However, there is no automatic increase in demand which will occur just because total supply is now higher, and until this newly created capacity is utilized through higher demand no social benefits are realized.

There is an economic mechanism through which increased supply does create its own demand. Greater R & D spending leads to an increase in productivity, primarily in the manufacturing sector. As a result of this increase, less labor is needed per unit of output. This in turn lowers unit labor costs, which leads to lower prices. Yet this decrease is not immediately transferred into higher output and employment. As prices are lowered (or grow at a less rapid rate), real disposable income of consumers increases at a faster rate. Consumers can then purchase a larger market basket of goods and services, which in turn are now available because the production possibility frontier has moved outward. Yet these decisions are not instantaneous and friction-less, as they would be in an oversimplified static model. We do not see significant effects of increased technology on aggregate demand until 1980.

Results of Macroeconomic Simulations

Once the increase in productive capacity has worked itself into aggregate demand through the mechanisms discussed above, real growth is then fairly steady as can be seen from Table 6. In particular, we find that real GNP rises near $5 billion per year faster than would be the case under the

Chase Econometric Associates, Inc.

Base = baseline projection with current estimates of NASA R & D spending for next decade.

NASA = an increase of $1 billion in 1958 dollars in NASA R & D spending.

Change = NASA - Base

% Change = $\frac{\text{NASA - Base}}{\text{Base}}$ Since the unemployment rate is already given in percentage terms, we do not calculate this item for unemployment.

Chase Econometrics

baseline simulation which does not include increased NASA R & D spending. Thus constant-dollar GNP is $6 billion higher in 1980, $10 billion in 1981, $14 billion in 1982, $18 billion in 1983, and $23 billion higher in 1984. If we were to continue this simulation farther into the future, we would find that the gap between GNP in the two simulations would continue to increase at approximately $5 billion per year--$28 billion in 1985, $33 billion in 1986, and so on.

As greater productivity is translated into higher demand, we find that the economy can produce more goods and services with the same amount of labor. This has two beneficial effects. First, unit labor costs decline, hence lowering prices. Second, lower prices enable consumers to purchase more goods and services with their income, hence leading to further increases in output and employment.

We find that the consumer price index grows at a slower rate with higher NASA R & D spending than without, and is a full 2% lower by 1984 than would otherwise be the case. Once again, this change does not occur in the early years of the simulation, but begins to become important in 1980.

One of the major effects of the higher level of real GNP and aggregate demand is the reduction in the unemployment rate of 0.4% by 1984. Since the labor force will be approximately 100 million strong by that date, this indicates, as a first approximation, an increase of 400,000 jobs. However, if we take into account the increase in the size of the labor force, the total will rise to 0.8 million new jobs. The increase in the labor force will occur for three principal reasons. First, the derived demand for labor will be greater because the marginal productivity of labor has increased. Second, the

Chase Econometrics

supply of labor will rise because the real wage has increased. Third, and probably most important, the increase in aggregate demand will reduce the amount of hidden unemployment as more entrants join the labor force.

It is also important to note that labor productivity rises substantially as a result of the increased NASA R & D spending. The index of labor productivity for the private nonfarm sector grows at a rate of 2.75% during the 1980-1984 period, compared to an average annual rise of 2.40% with no increase in spending. By 1984 the level of labor productivity is 2.0% higher than the baseline projection.

Further details and comparisons are given in Table 6 for a $1 billion increase in NASA R & D spending. We also calculated alternative runs for $0.5 and $0.1 billion and found that the results were approximately linear for other levels of spending change of equal or smaller magnitude. Similarly a decrease in NASA R & D spending of $1 billion would have reverse effects of the same magnitude on economic activity.

Significance and Reliability of Findings

Significance of Findings

One does not need an econometric model to show that an increase in government spending will raise GNP and lower unemployment. We learned many years ago that it is easy to spend our way out of a recession if no other constraints are involved. Yet having just recently come from the realm of double-digit inflation and the first postwar decline in labor productivity,

Chase Econometrics

it is clear that alternative policies must be examined not only from the point of view of their effect on demand and employment but on the real growth rate and the rate of inflation as well.

NASA R & D spending increases the rate of technological change and reduces the rate of inflation for two reasons. First, in the short run, it redistributes demand in the direction of the high-technology industries, thus improving aggregate producitivty in the economy. As a result, NASA R & D spending tends to be more stabilizing in a recovery period than general government spending.

Second, in the long run, it expands the production possibility frontier of the economy by increasing the rate of technological progress. This improves labor productivity further, which results in lower unit labor costs and hence lower prices. A slower rate of inflation leads in turn to a more rapid rise in real dispoable income permitting consumers to purchase the additional goods and services being produced and generating greater employment.

In assessing these results, we once again stress the importance of distinguishing between demand and supply effects. A $1 billion increase in NASA spending will have an immediate effect on real GNP, raising it approximately $2.1 billion the first year and $2.5 billion the second year. These demand multiplier effects are not markedly different than those which would have occurred for a similar increase in other purchases of goods and services by the government sector or for release of funds to the private sector for construction projects. They are, however, substantially higher than the effects which would be obtained from a $1 billion increase in transfer payments or low-productivity jobs programs. In particular we have found that the demand multiplier is smallest and the increase in inflation is largest for a

Chase Econometrics

unit change in transfer payments. When we turn to the supply side, however, the multiplier effects of lowering prices and increasing real income are more than twice as large. Other government spending programs which do not expand the production possibility frontier and improve productivity have no additional effect on the economy after the initial increase in demand.

Reliability of Findings

The results found for the equation estimating γ are all in agreement with economic theory, as the signs and magnitude of the coefficients are within the range expected from a priori expectations. Similarly, the statistical results indicate a high degree of correlation and no bias in the regression coefficients, or the goodness-of-fit statistics or the standard errors of estimate. In addition, the results are in accord with the findings of other econometric studies. Nevertheless, a number of criticisms have been raised about the final equation for γ, suggesting that the results might be significantly different if relatively minor changes were made to the function. These suggested changes focus on three areas; the choice of γ_C (the CEA series) instead of γ_D (the Denison series), the inclusion of the Cp term by itself and in conjunction with ORD, and the exclusion of the indexes of labor quality, particularly the level of education. To test the validity of these suggestions, we calculated sixty regression equations, including a "least favorable" case which incorporated all of the above changes. The sample period fits are somewhat worse, indicating that γ_D contains a larger random component than γ_C, but the coefficient of the term for NASA R & D spending is similar for these regressions. Even the "least favorable" case does not change the general conclusions of the study concerning either the rate of return or the economic impact of changes in NASA R & D spending.

REPORT OF THE COMPTROLLER GENERAL OF THE UNITED STATES

NASA Report May Overstate The Economic Benefits Of Research And Development Spending

The National Aeronautics and Space Administration commissioned Chase Econometrics, Inc., to evaluate how spending on NASA research and development affects the U.S. economy. Chase's report concluded that many benefits resulted from such spending between 1960 and 1974.

GAO assessed the Chase study to determine whether it successfully estimated the benefits of NASA spending. The study does not prove convincingly that the benefits are as large as stated.

Reproduced from U.S. General Accounting Office. NASA report may overstate the economic benefits of research and development spending. Washington, G.A.O., 1977. 53 p.

PAD 78-18

OCTOBER 18, 1977

COMPTROLLER GENERAL OF THE UNITED STATES
WASHINGTON, D.C. 20548

B-164912

The Honorable William Proxmire
Chairman, Subcommittee on
HUD-Independent Agencies
Committee on Appropriations
United States Senate

Dear Mr. Chairman:

Pursuant to your request of September 15, 1976, we have prepared an independent assessment of the NASA-commissioned report entitled "The Economic Impact of NASA R&D Spending," issued by Chase Econometrics, Inc. In May 1977, we sent you a draft copy of our report to assist you in your appropriations hearings. Our final report presents the same assessment along with NASA's and Chase's comments. In general, both agreed with our conclusions.

As agreed with your office, we expect to release the report to the public in about 7 days.

Sincerely yours,

Elmer B. Staats

Comptroller General
of the United States

REPORT OF THE
COMPTROLLER GENERAL
OF THE UNITED STATES

NASA REPORT MAY OVERSTATE THE ECONOMIC BENEFITS OF RESEARCH AND DEVELOPMENT SPENDING

D I G E S T

The National Aeronautics and Space Administration (NASA) contracted with Chase Econometrics Associates, Inc., to evaluate how Government research and development spending, particularly NASA's, affects the U.S. economy.

Chase's report "The Economic Impact of NASA R&D Spending" concluded that this spending produced many benefits between 1960 and 1974. The study did not try to evaluate how effectively NASA carried out its primary objectives, such as space exploration and satellite communication. NASA cited the Chase study in its 1976 appropriations hearings as evidence of certain beneficial effects of research and development.

The Chase study does not prove convincingly that the benefits are as large as stated. The study is useful as exploratory research, but other types of studies are necessary to provide a complete evaluation of NASA research and development.

The most significant conclusion of the Chase study is that "* * * a $1 billion sustained increase in NASA R&D spending will raise real GNP $23 billion by 1984 * * *." Of this estimated increase, $21 billion would result from improved technology and productivity, and the rest would result from increased Government spending, which stimulates spending in different parts of the economy.

Since similar increases would result from Government spending on other projects, such as welfare programs, the "multiplier effects" alone do not justify more NASA research and development spending. For this reason, GAO focused on projected technological improvements.

Tear Sheet. Upon removal, the report cover date should be noted hereon.

RECOMMENDATION TO THE ADMINISTRATOR OF NASA

Future evaluation studies should look at specific innovations, their effect on specific industries, and the process by which NASA expenditures for research and development improve productivity in the economy. In other words, some of the more important innovations, rather than the total budget, could be examined, and individual technological improvements in individual industries, rather than gross national product figures, could be studied. GAO believes that such studies would give the Congress a more accurate picture of what taxpayers are getting for their money.

MATTER FOR CONSIDERATION BY THE CONGRESS

Technical studies are frequently presented to the Congress in support of agency budgets and as evidence for or against proposed legislation. When important questions are at stake, such studies should be subjected to independent examination and appraisal.

AGENCY COMMENTS

In general, NASA as well as Chase Econometrics, Inc., agreed with our assessment of the Chase report. (See ch. 5.)

The Chase conclusions are questionable from three points of view:

--The results, even if accepted as accurate, do not provide the type of information needed to determine whether NASA's spending should increase or decrease. The estimates are of average, rather than incremental, effects. Therefore they do not show whether more spending for research and development would result in as many benefits as before. Within NASA's budget, the most productive or unproductive projects or types of spending have not been spelled out.

--Even if the Chase approach is accepted, the techniques used had certain shortcomings. Plausible and seemingly minor changes in the study's assumptions lead to major changes in the results. Under some of these alternatives, NASA research and development seemed to have no great effect on productivity. Such sensitivity to small changes in methodology indicates considerable uncertainty in Chase's results.

--Basically, the results depend upon statistical correlation between NASA research and development spending and changes in a measure of gross productivity in the U.S. economy. No information on specific NASA projects or on the adoption of new techniques by private business is used in the study. Because of problems in measuring total productivity in the economy and because other possible causes of technological progress were ignored, the correlations may not indicate a true cause-and-effect relationship.

Although the methodology of a particular study may be questioned, the importance of evaluating NASA's programs is undiminished. NASA has clearly been an important source of technical progress in recent years.

CHAPTER 1

INTRODUCTION

The National Aeronautics and Space Administration (NASA) spent about $40 billion on research and development (R&D) between 1961 and 1974. This represented 12 percent of total R&D spending in the United States during that period. Realizing that NASA's research findings could have wide application throughout the economy, the Congress directed NASA to "* * * provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

NASA's findings have had countless applications--in cardiac pacemakers, insulation materials, integrated circuits, gas turbines, and many more. Little is known, however, of the magnitude of these "spinoff" benefits to the economy. Chase Econometrics, Inc., prepared a report "The Economic Impact of NASA R&D Spending" for NASA evaluating these effects. The report concluded that NASA has a very favorable impact on the economy.

We were requested to "* * * evaluate the appropriateness of the study's assumptions, its analytical techniques, and the validity of its conclusions."

SCOPE OF REVIEW

In making this review, we

--analyzed the Chase report and, for background, some other NASA studies of R&D spillovers;

--replicated some of the statistical analysis of the Chase report to obtain certain measures of statistical significance and to see how sensitive the conclusions would be to changes in the basic assumptions; and

--discussed the report with NASA and Chase officials, and several other experts on the economics of R&D.

CHAPTER 2

THE PROBLEM OF R&D EVALUATION AND HOW THE CHASE REPORT TRIES TO SOLVE IT

THE PROBLEM OF EVALUATING GOVERNMENT-SPONSORED R&D

The Federal Government finances research and development in addition to that carried out by the private sector. The usual reasons for private R&D spending are future sales and profitability. Private firms tend to ignore benefits that would accrue to other firms (unless they can receive royalties) or to society as a whole. These are known as "spillover" benefits. Also, private firms may emphasize projects with short-term payoffs. Additional R&D spending by NASA or other government agencies, it is argued, could provide benefits to the Nation in excess of costs and thereby in some sense increase total benefits to society.

This analysis is similar to that supporting government regulation of pollution--an individual firm may fail to consider the harmful results of its activities if it does not have to bear the costs. Society may benefit by inducing the firm to reduce the pollution it causes. The R&D argument is the other side of the coin--that the government can increase benefits to society by inducing the firm to carry out more R&D or by doing the R&D itself.

The above argument for government involvement is valid, but it leaves the practical problem of deciding how much and what type of R&D to sponsor. First, the benefits that can be expected from the R&D must be estimated. There are many types of benefits--new products, greater productivity, lower costs--all of which are difficult to measure. Similarly, there are many types of R&D--such as medical, aerospace, and electronic--and analysis of aggregate R&D may not be very helpful to government decisions in specific sectors. In any case, predicting the results of any particular research activity is difficult. Examining the results of past programs may suggest productive new R&D ventures, but it will not provide exact measurements of future benefits.

WHAT THE CHASE REPORT SAYS

The Chase study has three main parts corresponding to the types of economic impact of R&D spending.

Section 2: Short-term economic impact. The NASA spending is directed toward certain high-technology industries and naturally affects them more than other parts of the economy. There are also short-term "multiplier" effects of the spending. Chase reports that keeping the Federal budget constant, while shifting more dollars to NASA, would cause the gross national product (GNP) to increase slightly as the dollars spent move through the economy.

Section 3: Long-run economic impact. The Chase study says that NASA R&D spending affects technological progress and results in higher productivity in the economy.

Section 4: Macroeconomic impacts. Here, the estimated improvements in productivity plus the multiplier effects of hypothetical higher NASA spending are analyzed together, using the Chase Econometrics Macro model to estimate effects on GNP, inflation, unemployment, etc. The study concludes that "* * * a $1 billion sustained increase in NASA R&D spending will raise real GNP $23 billion by 1984 * * *." Of this estimated increase, $21 billion comes from technological progress and $2 billion comes from multiplier effects of increased government spending.

The results in section 2 are, in our judgment, reasonable estimates, in accord with widely accepted economic analysis. These effects are small, however, and they are not "benefits" in the strictest sense. Rather, they are measures of induced increases in the level of economic activity. As such, they are not crucial to deciding whether more or less money should be spent on NASA R&D, because similar effects could be obtained by other forms of government spending--such as defense procurement or energy R&D. Tax cuts are, of course, a comparable alternative, although the size of their impact may differ. Because the results in section 2 are not particularly controversial or critical to budgetary decisions, we do not discuss them further in this report.

The results in section 4 depend upon section 3, but they are basically elaborations of the macroeconomic effects of section 2.

Section 3 is the heart of the Chase report because it estimates economic benefits (in the form of increased productivity) as opposed to impacts on the economy (which may be neutral rather than beneficial). Government spending for certain goods causes some industries to grow in relation to other industries. Policymakers should be aware of such

impacts, but such impacts are not necessarily a worthy goal of government policy. On the other hand, increased productivity in the economy is clearly beneficial. Therefore, the remainder of our report deals with this important topic.

HOW THE CHASE REPORT REACHED THESE CONCLUSIONS

Chase Econometrics attempted to test the theory that NASA R&D (among other factors) affects the rate of technological progress in the U.S. economy. Testing this theory requires a measure of technological change, a subject on which considerable research has been done. The Chase study uses a productivity measure based on a data series for "potential" GNP developed by the Council of Economic Advisors. Potential GNP is that which could be achieved if all labor and capital were fully employed. Potential GNP has grown steadily over the years, partly because of increases in the available quantities of labor and capital. The rest of the growth of potential GNP is the result of improvements in productivity; that is, growth in the level of output per unit of input. The statistical measure of productivity growth is a residual factor--it represents increases in potential GNP not due to increases in the available quantities of labor and capital.

The next part of the theory is that increases in productivity result from several explanatory variables:

--NASA R&D expenditure as a percentage of GNP.

--Other R&D expenditures as a percentage of GNP.

--An index of "industry mix" to measure the effect of different rates of technological growth in different industries.

--An index of labor quality (for which no significant statistical effect could be identified).

--An index of capacity utilization.

The Chase hypothesis is that if this theory is true (that these variables affect technological progress), then an empirical test of the theory would yield statistically significant results. That is, there will be a statistical pattern of correlation between the "causes" and the "effect."

It is logical to assume that R&D will not affect technological progress as soon as the R&D money is spent, but

will have a delayed effect spread over several years. Chase uses statistical methods intended to allow for this delayed effect.

Within this theoretical framework, there are many possible variations in statistical testing. For example, variables can be measured in different ways, data from different time periods can be used, and variables can be added, left out, or combined in different ways. Chase experimented with many of these variations, finally selecting a statistically estimated equation that Chase believed best expressed the underlying theoretical considerations. Chase's "preferred" equation supported the theory that NASA R&D has had a significant effect on technological progress.

CHAPTER 3

CRITIQUE OF THE STUDY'S STATISTICAL FINDINGS

Even if the Chase Econometrics approach is accepted, certain statistical problems cast doubt on the results. In replicating the statistical analysis, we found that plausible and seemingly minor changes in the study's assumptions led to significant changes in the results. (See app. II for details.) Under some of these alternative assumptions, NASA R&D apparently had no significant effect on productivity. Here, as throughout this report, we take no position on the actual magnitude of NASA's impact. The point is that the great sensitivity of the Chase report results to small changes in methodology indicates considerable uncertainty in the Chase conclusions. We believe that the findings should be insensitive to slight changes in the methodology.

The key number in the Chase conclusions is the estimated coefficient of NASA R&D spending--the "NASA effect." In Chase's "preferred equation," this figure is estimated to be 0.426. Chase's interpretation is that a $1 billion increase in NASA R&D spending would eventually increase the total capacity of the U.S. economy by $4.26 billion. Another interpretation by Chase is that this represents a 43-percent rate of return on investment in NASA R&D.

This conclusion, if accepted, would indicate an enormous impact on the economy. The literal interpretation is that, if NASA had spent nothing on R&D, productivity would have declined in the United States between 1965 and 1974. That is, NASA R&D is given credit for all of the Nation's productivity growth, and more besides.

Minor alterations in the Chase techniques, however, lead to lower estimated values for the NASA effect. In some cases, the estimated value of the key coefficient is not much above zero, which would indicate no discernible impact.

To investigate the sensitivity of the Chase results to changes in some of the statistical assumptions, we replicated the Chase statistical analysis. Using the same data and the same basic statistical techniques, we estimated several different regression equations that we believed to be as plausible as or more plausible than Chase's preferred equation. (See app. II.)

Our results are summarized as follows:

1. Chase's preferred equation uses data from 1960 to 1974. If data from 1956 to 1974 were used, the estimate of the effect of NASA R&D drops 25 percent to 0.318.

In general, using the longer period is preferable because the larger the sample, the smaller the likelihood of spurious correlation. The Chase report prefers the shorter period because NASA R&D spending was negligible from 1956 to 1959.

We believe that including a period in which NASA spending was negligible is advantageous because this gives a wider range of values to NASA R&D spending. To see why this is worthwhile, consider the opposite case: If NASA R&D had been exactly, say, $2 billion each year for 10 years, an examination of data for that period would yield no information on the effect of changes in NASA R&D, for no changes would have occurred. Only by including a variety of values in the sample can the cause-and-effect relationship be observed and measured.

2. The Chase report makes certain adjustments for the level of capacity utilization in the economy. Alternative adjustments, which we consider superior, cause significant changes in the main results.

3. Chase's preferred equation does not include changes in labor quality as a possible influence on productivity. The Chase report noted that variables representing labor quality did not significantly affect productivity. We believe that labor quality should be considered in the statistical estimation procedures. If it had, the estimate of the "NASA effect" would have been about 33 percent lower for 1960-74 and 16 percent lower for 1956-74.

4. When we incorporate all of the changes we believe to be improvements, the estimated value of the NASA R&D coefficient drops to 0.136--a figure less than a third as large as Chase's estimate. Furthermore, the statistical measure of significance falls to a level that can be interpreted as "insignificant." That is, in our equation the observed relation between NASA R&D and productivity growth is indistinguishable from a relation that might be observed by chance between two unrelated data series.

We emphasize that this is not "proof" that NASA R&D has no effect on productivity. But such findings cast doubt on the Chase methodology.

5. Finally, the Chase results may be questioned because of a statistical problem called "multicollinearity." This problem occurs when two variables that are supposed to affect the dependent variable (in this case "productivity") are closely correlated. In such a case, distinguishing between the separate effects of the two variables is difficult. In fact, NASA R&D is highly correlated with other R&D expenditures between 1960 and 1974. This correlation casts doubt on the accuracy of the estimate of the NASA effect; it is also largely responsible for the sensitivity of the estimates to slight changes in the assumptions.

In statistical work of this type, there are many possible alternative assumptions. We reestimated the Chase equation making certain changes that we considered improvements to the Chase approach. Our estimate of the "NASA effect" was considerably lower than that of the Chase study. Such results do not, in any sense, prove that the NASA effect is zero; they merely fail to identify such an effect.

At this stage, it is well to repeat that we believe that NASA has had certain beneficial effects on the economy, but that such effects are not well measured by the Chase method.

CONCLUSION

The results of the Chase study are sensitive to plausible and minor changes in the methodology. Under some assumptions, it could be concluded that NASA R&D had no significant effect. We, therefore, conclude that the Chase study does not sufficiently substantiate its findings on the effect of NASA R&D on productivity.

CHAPTER 4

CRITIQUE OF THE STUDY'S BASIC APPROACH

PROBLEMS WITH THE STUDY'S METHODS

The basic findings of the Chase Econometrics study depend upon statistical correlation between NASA R&D spending and changes in a measure of productivity for the entire economy. The data on these two variables shows that NASA R&D reached its highest levels in 1966-68 and that the highest rates of productivity change occurred in 1970-72. Since (in the Chase preferred equation) the data studied covers only 1960 to 1974, these two changes dominate the analysis and are responsible for the correlation discovered. Indeed, extending the analysis to include data from earlier years weakens the findings. Although this correlation may suggest a cause-and-effect relationship, it should not be interpreted as a precise measure of the NASA effect.

Figure 1 shows the basic data series that Chase worked with. (Other variables were also used in the analysis.) Productivity growth is explained mainly by NASA R&D and by other R&D, expressed as a percentage of GNP. As the graph shows, productivity growth has varied during the period illustrated. A main conclusion of the Chase study is the statistical correlation between NASA R&D and productivity growth. The two data series are virtually uncorrelated with each other, but this is plausible; it would probably take several years for R&D spending to affect productivity. Thus, Chase determined that the peak in productivity growth (1971) was caused by the peak in NASA R&D (around 1967).

The series on productivity growth has fluctuated irregularly for as long as the data has been available--over 60 years. In this broader context, how reasonable is it to ascribe the latest upsurge in productivity almost entirely to an increase in NASA R&D? As mentioned in chapter 3, including only 4 more years of data in the analysis reduced the estimated impact of NASA R&D by 25 percent.

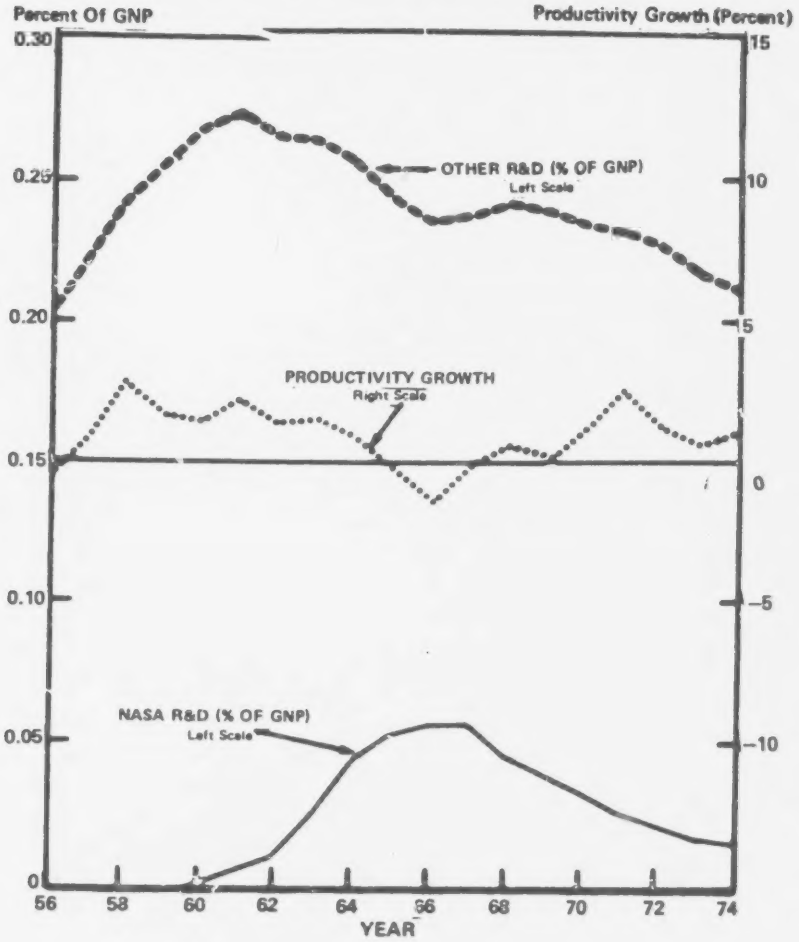
Figure 1 illustrates two more aspects of the basic data:

--NASA R&D is a small portion of total R&D--about 12 percent between 1961 and 1974. Yet this portion is held responsible for all of the productivity growth.

--Other R&D declined at about the same time that NASA R&D increased. This creates the statistical problem,

Figure 1

PRODUCTIVITY GROWTH
NASA R&D AND OTHER R&D
(AS DEFINED BY CHASE ECONOMETRICS)



mentioned in chapter 3, that makes it difficult to separate the effects of the two types of R&D.

In the Chase study, the main effect of NASA R&D is assumed to be raising the level of productivity in the economy; that is, increasing the total product (measured in dollars) that could be produced with available labor and capital. This does not directly measure the benefits resulting from improvements in products, except insofar as consumers demand fewer of the improved products and thereby release capital and labor to produce more of other products. Similarly, the value of new products is not well accounted for. If a new and better product replaces an old product that cost the same amount to produce, the GNP figures will not show the benefit. These criticisms of the Chase methodology point up inherent problems in using GNP as a measure of welfare.

The study does not use data on specific NASA projects or on the adoption of new techniques by the private sector. Rather, the data are on such an aggregate level that nothing about NASA is measured directly except its budget. More information, we believe, could have been used to advantage. As it is, the empirical work rests upon a theory--that more NASA R&D will cause more growth in productivity--which has little analytical support. Economists who have reviewed the study have asserted that the process of technological change is considerably more complex than the Chase study implicitly assumes.

USEFULNESS OF THE STUDY'S RESULTS

Granted that the Chase study has merit as exploratory economic research, how useful are its results to the budget process? Do the study's results, even if accepted as accurate, provide the information needed to determine whether NASA's budget should increase or decrease?

Any government program that produces a 43-percent rate of return would certainly be worth continuing. This greatly exceeds the average rate of return in the private sector. Still, the occurrence of past spinoffs does not insure that future spinoffs will occur at the same rate as new and different R&D projects are sponsored. New projects would still have to be justified on their own merits.

Two aspects of the Chase approach should be noted. First, the estimates of NASA's effect are average, rather than incremental, amounts. Even if it is granted that NASA's spending in 1965, for example, produced certain benefits, it

does not follow that increasing that year's budget by, say 20 percent, would have increased the benefits by 20 percent. More likely, the increase in benefits would have been less than 20 percent.

In any year, NASA considers many possible R&D projects. If NASA pursues those it judges to be the most productive, then increasing its budget would allow it to pursue one or more of those projects that it had previously rejected as below average in prospective payoff. To state the same principle of "diminishing returns" somewhat differently, it is likewise possible that, even in a year when NASA's projects produced great benefits, a few unproductive projects could have been eliminated, thereby reducing the budget without reducing benefits.

In any case, efficient budget management requires project-by-project evaluation. Whatever the merits of an overview of the impact of the entire agency budget, such an approach misses this necessary detail.

Second, when discussing the usefulness of this approach, one should keep in mind that much of the Chase report was devoted to macroeconomic and interindustry impacts of NASA R&D spending. Any form of government spending produces some such effects, and the differences among these effects are not crucial to allocating public funds to a particular agency.

IN DEFENSE OF THE CHASE METHOD

The merits of the Chase approach stand out more clearly when the alternatives are considered. Studying the effect of NASA R&D on a totally disaggregate basis involves many problems:

--Assessing the impact of every NASA R&D contribution would be prohibitively expensive, but choosing just a few would not necessarily give an accurate picture.

--Major technical innovations are spread through many segments of the economy and their effects are not felt for several years. It is doubtful that all of the effects could be accounted for in studies of individual projects.

The Chase approach at least attempts to measure the diffuse effects, although not with total success. The Chase study is not a definitive budget justification, but it is a worthwhile exploratory approach to a difficult problem in economics.

We believe that some compromise is possible between the Chase approach and the project-by-project approach. This would involve studying technical progress in the industries for which NASA R&D has been particularly important. NASA officials said some such studies are being considered.

RECOMMENDATION TO THE ADMINISTRATOR OF NASA

We recommend that the Administrator see that future evaluation studies take a less highly aggregated approach. That is, the researchers should

--analyze the process by which NASA R&D expenditures improve productivity in the economy;

--study some of the more important innovations, rather than the total R&D budget; and

--study individual technological improvements in particular industries, rather than GNP figures.

This kind of research would not produce a single measure of the total impact of all NASA R&D, like the $23 billion figure given by Chase. Indeed, accurate and meaningful aggregations of this kind may not even be feasible. But we believe that the results of a number of disaggregated studies would give the Congress a more accurate and informative picture of what taxpayers are receiving in return for their money.

MATTER FOR CONSIDERATION BY THE CONGRESS

Technical studies are frequently presented to Congress in support of agency budgets and as evidence for or against proposed legislation. We believe that, when important questions are at stake, such studies should be subjected to independent examination and appraisal.

CHAPTER 5

NASA AND CHASE COMMENTS AND OUR RESPONSE

We asked both NASA and Chase Econometrics to comment on our report. In general, both agreed with our conclusions. (See apps. III and IV.)

Some NASA comments leave the impression that our objection was merely over which of the alternative estimates is the most acceptable and that the estimate we chose still shows a high rate of return to NASA R&D spending. This is, however, not our point.

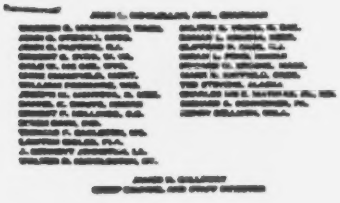
The logic of our analysis is as follows:

--In chapter 4, we argue that the approach taken by Chase will not answer the basic questions. Productivity is a complicated function of so many variables, current and lagged, that explaining it by a few variables will not provide meaningful information on cause-and-effect relationships. We doubt whether statistical investigations of time series data on GNP will ever measure the relation between R&D spending and productivity with the precision sought by the Chase study.

--In chapter 3, we assume, for the sake of argument, that the approach taken by Chase is acceptable. We conclude that minor respecification of Chase's preferred equation to produce a more plausible model results in a lower rate of return for NASA R&D on the one hand, and the possibility of no NASA productivity effect on the other. In NASA's words, "the variables selected may statistically interact to cloud the validity of the results." With the Chase result (a 43-percent rate of return), this is clearly the case. Though the validity of our result (a 28-percent rate of return) does not suffer from this particular statistical deficiency, it should not be taken at face value either, for reasons cited in this report.

38-036 O - 84 - 23

APPENDIX I



United States Senate

COMMITTEE ON APPROPRIATIONS
WASHINGTON, D.C. 20510

September 15, 1976

Honorable Elmer Staats
Comptroller General of the United States
General Accounting Office
441 G Street, N. W.
Washington, D. C. 20548

Dear Elmer:

At the Appropriation hearings for fiscal 1977, before the Subcommittee on Housing and Urban Development and Independent Agencies of the Committee on Appropriations, NASA presented to the Subcommittee, in support of its budget request, a study entitled: "The Economic Impact of NASA R&D Spending." This study, commissioned by NASA and performed by Chase Econometrics, Inc., concluded that NASA R&D spending has a substantial beneficial impact on the economy.

Although we find this study a useful input to our hearings, we would like the GAO to make a careful assessment of that study. This would give the members of the Subcommittee an independent view of the impact of NASA functions on the economy.

In your assessment of the study, we would like the GAO to evaluate the appropriateness of the study's assumptions, its analytical techniques, and the validity of its conclusions.

For your report to be timely, we would like to have it available to the Subcommittee before its Appropriations hearings that will be held in February or March of 1977. While NASA comments might be useful, the process of obtaining them should not delay the completion of the report beyond the time that it is needed. If you have any questions concerning this request, please contact Mr. Thomas van der Voort of my staff.

Sincerely yours,

William Proxmire, Chairman
HUD-Independent Agencies Subcommittee
Senate Appropriations Committee

TECHNICAL APPENDIX TO CHAPTER 3

The Chase Econometrics "preferred equation" was one of many equations which were devised to determine the contribution of NASA R&D expenditures to the rate of technological change. The coefficient estimates which Chase produced from these equations may be found in table 3.13 on pages 87 and 88 of their report. Chase did not, however, present summary statistics of the range of error associated with coefficient estimates in alternative equation forms. These statistics describe the range of variability of the coefficient estimates and measure the range within which the true measure of the effect probably lies. The range of error associated with the Chase estimates of NASA R&D productivity effects in alternative equation forms is particularly important in view of the report's conclusions. We reproduced Chase's methodology in order to determine the range of error associated with coefficient estimates for NASA R&D in alternative equation forms that we believe are more plausible on both economic and statistical grounds.

Our reproduction of the Chase methodology should not be construed as an endorsement of a macroeconomic approach to measuring NASA-induced productivity changes. We are simply examining the following problem: If a macroeconomic approach is acceptable, how reliable are the estimates of the NASA contribution to the rate of technological change and how sensitive are these estimates to minor respecification of equations or variables that produce a more plausible model.

VARIABLES USED BY CHASE ECONOMETRICS

Chase used the following variables as proxies for the rate of technological change and for theoretical influences.

Dependent variable

Gamma - Council of Economic Advisors rate of technological change based on trend, adjusted for full employment of labor and capital resources.

Independent variables

NRDA - Almon weighted ratio of NASA R&D expenditures to GNP.

ORDA - Almon weighted ratio of other R&D expenditures to GNP.

ORDC - Almon weighted ratio of other R&D expenditures to GNP, weighted by a standardized measure of capacity underutilization.

IM-$\overline{IM}$ - Deviations of a Chase-designed industry mix variable from its mean. This variable is intended to account for resource shifts from low-technology to high-technology industries and vice versa.

CP-$\overline{CP}$ - Deviations of the Chase index of capacity utilization from its mean.

ΔIE - First differences in an index of labor quality as affected by education.

ΔIAS - First differences in an index of labor quality as affected by age-sex mix of the labor force.

Chase measured these variables over a period from 1956 to 1974. They were intended to measure five categories of influences on the rate of technological change, including (1) labor quality, (2) utilization of productive factors, (3) resource transfers which, when incorporated in high-technology industries, may be expected to increase the rate of technological change, (4) R&D expenditures, and (5) a dynamic or lagged response of the rate of technological change to increases in R&D expenditures. These determinants seem sound on theoretical grounds and may include all possible determinants.

RESULTS

Chase's preferred equation estimates the contribution of NASA R&D expenditures to the rate of technological change, includes the capacity weighted other R&D variable (ORDC), omits labor quality proxies (ΔIE and ΔIAS), and includes only observations for 1960 to 1974.

We believe that a more theoretically justifiable equation for measuring NASA-induced productivity changes would include labor quality proxies, an unweighted measure of other R&D expenditures (ORD), since the capacity transformation of this variable (ORDC) is questionable and leads to very complex interpretation of results. Also, we used observations for 1956 to 1974.

Our results are presented in table 2. The Chase results for the Chase preferred equation and for our preferred equation are presented as equations 1 through 4. These results are followed by our estimates of those same four equations (equations 5 through 9). Comparison of our results with Chase's results shows that we have very closely reproduced its methodology for both sample periods.

Choice of sampling period

Correlation matrices for the variables we used in each sample period are presented in table 1. The correlation coefficient between the R&D variables that Chase employs in its preferred equation for 1960 to 1974 is very high (0.817). When collinearity is this high between two variables, sorting out the separate effects of each is impossible. Because of this, the coefficient estimates that Chase presents in table 3.13 of its report are very sensitive to minor alterations in variable or equation form. The correlation coefficient between NRDA and ORDC is, however, only 0.267 for 1956-74, well within the range of acceptability. In comparisons of the matrices for each sampling period, the correlation coefficients between the critical pairings of R&D variables and between R&D variables and other included variables are more often lower over the longer sample period. The correlation coefficient for NRDA and ORDA is higher during 1956 to 1974 than during 1960 to 1974, but it is within an acceptable range. For these reasons, the longer sample period is preferred, particularly for estimating Chase's preferred equation.

Labor quality and other influences

In our preferred equation, NASA R&D enters without statistical significance for either sampling period. The coefficient on the other R&D variable is statistically significant for our preferred sampling period. When the Chase preferred equation for 1960-74 is altered only by substitution of a noncapacity weighted other R&D variable for the one Chase prefers, the coefficient on NASA R&D drops from 0.428 to 0.259 for 1960-74 and from 0.318 to 0.227 for the longer sampling period. The NASA coefficient remains statistically significant for both periods, however (equations 9 and 11). But the introduction of labor quality into these equations, though itself insignificant, causes the NASA coefficient to become statistically insignificant (equations 7 and 8).

APPENDIX II

When labor quality proxies are introduced into an equation which is in all other respects similar to the Chase preferred equation, the coefficient on the NASA R&D variable becomes insignificant for 1960-74 (equation 10) but remains significant during the longer sampling period (equation 12). The result for 1960-74 is caused by the instability of the NASA R&D coefficient which results from the high intercorrelation between the preferred NASA and other R&D variables during that period.

We reemphasize that our preferred equation is equation 8. Labor quality is included and, thus, the equation contains all Chase proxies for theoretical influences. Capacity utilization enters "on its own" and not combined with an obscure transformation of the other R&D variable. In this equation, the NASA effect is insignificant.

CONCLUSION

The Chase results are sensitive to both the manner in which the estimating equations are specified, the sample periods, and the manner in which R&D variables are measured. If NASA R&D spending has as strong an effect as the Chase study claims, then that effect should not be greatly altered in a more fully specified and more theoretically defensible equation.

Reply to Attn of W

Mr. R. W. Gutmann
Director
Procurement and Systems
Acquisition Division
U.S. General Accounting Office
Washington, DC 20548

Dear Mr. Gutmann:

Thank you for the opportunity to comment on the draft report entitled, "Review of 'The Economic Impact of NASA R&D Spending'," which was prepared by GAO's Program Analysis Division pursuant to a request of the Chairman, Subcommittee on HUD-Independent Agencies, Senate Committee on Appropriations.

NASA finds that the GAO analysis is well done and does not take issue with the results. The enclosure discusses the most important differences between the GAO analysis of the data used in this study and the Chase Econometrics analysis, which are based on the art of interpreting the statistical results.

Sincerely,

Kenneth R. Chapman
Assistant Administrator for
DOD and Interagency Affairs

Enclosure

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
COMMENTS ON THE GAO DRAFT REPORT
ENTITLED "REVIEW OF 'THE ECONOMIC
IMPACT OF NASA R&D SPENDING'"

The GAO finds that the Chase study does not:

- Provide information useful to budget makers which indicates the economic impacts of incremental changes in NASA R&D funding
- Present statistical results that are stable and accurate within acceptable levels of confidence
- Reveal a true cause and effect relationship between NASA funding and changes in total productivity

But the GAO recognizes and believes that:

- NASA has contributed significantly to the economic productivity of the nation
- The Chase study was valuable exploratory research into a difficult (and as yet) unsolved problem
- It would be valuable for NASA to continue doing economic evaluations of its programs, particularly at a more detailed industry and specific innovation level

The major methodological problem that the GAO had with the Chase study was the sensitivity of the results to relatively minor changes in the variables used for the regression analysis. With this in mind, they re-created the data base Chase used and re-ran the equations, testing for statistical significance.

The most important differences between the GAO analysis of the data used in this study and the Chase Econometrics analysis rest in the art of interpreting the statistical results. Chase chose a regression equation which when

analysed showed a 43 percent rate of return to NASA R&D funding. In their preferred equation the "NASA R&D" variable was statistically significant. The GAO chose an equation that included the greatest number of explanatory variables at the expense of the statistical reliability of the "NASA R&D" variable. They also used a longer time span which included a period without NASA spending as well as the period of heavy NASA funding which Chase had mainly emphasized. Interpreting the regression equation that the GAO prefers (which was one of the many equations Chase had analysed and rejected) yields a 28 percent rate of return to NASA R&D. This result is still well within a range of economic returns that can be considered very good investment of government R&D funds.

NASA accepts the GAO critique and its conclusions as being constructive, accurate, and objective. We agree that the data contain some inherent measurement problems and that the variables selected may statistically interact to cloud the validity of the results.

NASA recognizes that empirical measurement in economics is an inexact science and that the specific magnitude of the results of the Chase study is not as important a finding as the direction and the approximate range of returns. The GAO analysis does not change the basic conclusions of the Chase study. Their discussion tends to reinforce those conclusions since their data indicate that between 1966 and 1974 NASA has (when NASA funding was having its full effect) contributed to productivity about 26 percent as much as all other R&D combined. This can favorably be compared to the fact that NASA in those same years was funding only 12 percent of all of the R&D investment in the nation.

NASA agrees that the macroeconomic approach to economic evaluations of impacts has limitations. The GAO points these out, but also recognizes that the alternatives to providing similar policy conclusions are not feasible. They are also aware that the Chase approach is based on standard and supportable economic theory.

APPENDIX III

NASA finds that the GAO analysis is well done and does not take issue with their results. Their suggestions for further analysis have helped in the planning already underway within NASA for doing more detailed microeconomic and macroeconomic studies, which will improve on the past analyses.

Mr. Harry S. Havens
Director
Program Analysis Division
United States General Accounting Office
Washington, DC 20548

Dear Mr. Havens:

Thank you for your letter of June 1 and the accompanying draft of your report entitled "Review of 'The Economic Impact of NASA R&D Spending.'"

I have read your review and must say that I find it to be fair to all sides concerned. We did experiment with some 60 different regression equations and found that the critical coefficient of NASA R&D spending did not vary as much as you have indicated. However, I would certainly not rule out the fact that it is possible to choose other combinations of variables in that regression, although you did not list these specifically.

I appreciate your giving me the opportunity to review this draft.

Sincerely yours,

Michael K. Evans

1450	Repayments	−26,296	−30,100	−176,700
1490	Outstanding, end of year	757,749	932,649	792,649

This appropriation provides for the following research, development, procurement and operations activities of the National Aeronautics and Space Administration:

1. *Space transportation systems (STS).*—The objectives of this activity are focused on production and operations of the Space Shuttle vehicle and other elements of a Space Transportation System. The elements of the program are described below along with work to be performed during 1984.

(a) *Space transportation capability development.*—The first reusable Earth-to-orbit vehicle is the key element in the Space Transportation System. The Shuttle has unique capabilities not available with expendable launch vehicles, including retrieval of satellites, experiments and equipment for reuse; maintenance and repair in orbit; and reuse of space laboratories. Cost effective operations of the Shuttle will allow increased versatility and productivity of space operations for all users.

In 1982, the Shuttle successfully completed the final two orbital flight tests of the four scheduled in the development program and was declared operational by the President on July 4, 1982. The Shuttle's actual flight performance fulfilled the hopes and expectations of its designers. In spite of minor technical problems which were to be expected during the developmental phase, the overall system worked extraordinarily well. The first operational flight was successfully flown in November 1982.

The second orbiter, Challenger, was delivered on schedule in July 1982 to the Kennedy Space Center. The fabrication of the third and fourth orbiters—Discovery and Atlantis—is underway, and these orbiters will be delivered in late 1983 and late 1984, respectively. In 1984, the principal activities to be conducted in Shuttle Production and Capability Development, in addition to production of the flight orbiters are: testing of the main engine for continuing operations at full-power level; continuing procurement of the initial orbiter flight spares and crew equipment; initiation of procurement of orbiter structural spares; installation of manufacturing tools for the external tank and solid rocket booster which will enhance their production rate capability; and continuing analyses of flight performance data from operational flights to improve understanding of the vehicle dynamics. In addition, work will continue on the development of a new structural case for the solid rocket motor made of composite materials and the necessary modifications to the orbiter and launch site

facilities for a new, high energy upper stage called Centaur.

The other principal areas of activity in Space Transportation Capability Development include NASA efforts related to the Spacelab, and upper stages to place satellites in higher altitude orbits; the engineering and technical base support at NASA centers; advanced programs study and evaluation efforts; and payload operations and support equipment.

The Spacelab, a joint effort with the European Space Agency (ESA), will be carried in the cargo bay of the Shuttle orbiter and will provide users with a multipurpose, reusable space laboratory. ESA is funding the development, production, and delivery of the first Spacelab and associated ground support equipment; NASA is providing for development of auxiliary flight and ground support equipment and procurement of additional sets of flight hardware and ground support equipment necessary to meet its mission requirements. Also included is funding to continue procurement of a second Spacelab from ESA. The first dedicated Spacelab flight is planned for launch in September 1983, with the second planned for September 1984.

Also continuing is the development, procurement, and integration of the Centaur upper stage in a joint development program with the Department of Defense. This stage will be used with the Shuttle for some planetary missions and for those Earth orbital missions requiring altitudes beyond the basic Shuttle capability and in excess of that provided by the other existing upper stages.

In advanced programs, two significant efforts will be pursued: initiation of development on a tethered satellite system, a new joint program with the Italian government, and continuation of studies related to a possible future Space Station. Other efforts will focus on technical and programmatic data for the definition and evaluation of potential future space missions and systems.

(b) *Space transportation system operations.*—This activity provides for the operation of the Space Shuttle and the expendable launch vehicles.

In 1984, STS operations efforts will continue the procurement, assembly, and checkout of the solid rocket boosters and external tanks, as well as standardized flight plans, avionics software, flight control systems, and crew procedures. The preparations in the preflight and direct mission support elements at Kennedy Space Center, Lyndon B. Johnson Space Center, and Marshall Space Flight Center will continue.

In 1984, missions to be supported include the launch of payloads for the Department of Defense, domestic commercial and foreign communications customers, and NASA payloads. Among the major NASA payloads are the Large Format Camera, Materials Processing Experiments, the Long Duration Exposure Facility, the Earth Radiation Budget Satellite, the Spacelab-3 Mission, and the retrieval/repair of the Solar Maximum Mission Spacecraft.

In expendable launch vehicles, this effort provides engineering, reliability, and launch support for the Delta until the transition to Shuttle operations is completed.

2. *Space science and applications.*—This activity supports systematic study of the Earth and its space environment, the solar system, the galaxy and the universe; and the research and selected technology developments to encourage the practical application of space technologies to needs on Earth.

(a) *Physics and astronomy.*—Research is being conducted to investigate the Earth's environment, the Sun and the interplanetary medium, the galaxy and distant space, as well as the interrelationships among these areas and the processes that control them. Past results include discovery of the Earth's radiation belts and knowledge of phenomena such as pulsars, quasars, and black holes.

Highlights of 1982 include the successful flight of the first space science payload on the Space Shuttle, which gathered solar physics data, evaluated the ambient and induced Shuttle environment, and provided data on payload thermal control technology. In addition, the Cosmic Ray Isotope Experiment was launched on a Department of Defense satellite to carry out galactic cosmic ray research.

Development work is continuing on the Space Telescope, planned to be launched in 1985, which will allow research at the forefront of optical and ultraviolet astronomy for decades. Work is also continuing on the Gamma Ray Observatory (GRO) mission planned for launch in 1988. The GRO will provide the highest sensitivity study of the sky conducted in the gamma ray spectral region.

Development and integration efforts also continue for payloads to be flown on Spacelabs 1 and 2 flights planned for launch in 1983 and 1985, respectively. Development activities for follow-on Spacelab payloads are also underway. Several multiuser payloads to investigate phenomena in the various disciplines are now being defined for future Spacelab missions. Plans for 1984 include the Spacelab payloads for Physics and Astronomy, and the mission management requirements for all agency payloads. Work is also continuing on several Explorer projects to continue research thrusts started in prior years.

(b) *Planetary exploration.*—This activity increases scientific knowledge about the origin and evolution of our solar system and of life processes, and applies the results to a better understanding of the Earth.

Work is continuing on the Galileo mission to Jupiter; the spacecraft is composed of two segments—an orbiter and an atmospheric entry probe. The Galileo orbiter and probe will be launched in 1986 on a Centaur Upper Stage and will achieve Jupiter orbit capture in 1989 to carry out long-term studies of the giant planet, its satellites, and its magnetosphere. The probe will enter the upper atmosphere of Jupiter. Development work is also continuing on U.S. experiments to be flown on the International Solar Polar Mission being developed by the Europeans, to explore the heliosphere, the space around the Sun, and to obtain observations of the Sun (launch in 1986).

Design and development will be initiated on the Venus Radar Mapper (VRM) mission in 1984 which will utilize synthetic aperture radar to map the surface of

General and special funds—Continued

RESEARCH AND DEVELOPMENT—Continued

Venus. The mission is targeted for a 1988 launch on a Centaur class upper stage.

Studies will be continued during 1984 on future candidate missions. Analysis of data from past planetary missions will also continue, including data from the Voyager and Pioneer missions.

(c) *Life sciences.*—This program will continue to provide for the research and technology necessary to meet the goals of ensuring human health, safety, well-being, and effective performance in space flight; utilizing space environment to advance knowledge and applications in Earth medicine and biology; and understanding the origin and distribution of life in the universe.

(d) *Space applications.*—This program category conducts coordinated and logically phased research and development activities to relate space technology to Earth benefits. The 1984 program provides for continued progress in the areas of materials processing in space, remote sensing, and communications. The activities involve active and increasing participation and funding by current and future users of these capabilities, within the Government, industry, and the academic community. The highlight of 1982 was the successful launch of Landsat-4 which will advance technology in remote sensing of the Earth from space.

The Materials Processing in Space program will continue to support fundamental research using the unique environment of space to enhance our basic knowledge of materials processing and to determine if space techniques can be used to control the composition and shape of materials. The research program includes high temperature heat pipes, electrostatic positioning methods, laser holography, acoustic positioning systems, and furnaces for directional solidification with high temperature gradients.

In communications, the 1984 program includes continued development and operation of the search and rescue experiment, further definition of an applications data service, and continuation of advanced communications research activities, including initiation of the Advanced Communications Technology Satellite (ACTS) design and development efforts. This mission will be a joint Government/industry undertaking wherein industry will provide a significant contribution toward the cost of the mission. ACTS is targeted for launch by the Space Shuttle in 1988.

In remote sensing, utilization of data from satellite observations has resulted in an increase in our understanding of the Earth's resources and environment, and in our ability to forecast change. Recent achievements include the successful launch of Landsat-4, a new-generation satellite with a Thematic Mapper which is providing imagery with improved spectral and spatial resolution; development and testing of techniques to predict severe storms; and use of SEASAT satellite experiments to measure ocean surface winds, sea state, major ocean currents, ocean circulation patterns, and sea ice conditions.

A wide range of similar activities will be continued during 1983 and 1984. Mobile laser units are being deployed in the United States, Australia, and the Pacific to form a global network for observation of tectonic plate motion. Ongoing efforts in the remote sensing area include analysis of data from the Landsat-4 Thematic Mapper and development of ground system capability; the Earth radiation budget experiment to acquire valuable data for climate studies, and the development of upper atmospheric research instruments. This group of instruments will provide the capability to obtain a global data set for studying the interaction between chemistry, radiation, and dynamics of the upper atmosphere.

3. *Technology utilization.*—This program is designed to facilitate the transfer of NASA technology to the nonaerospace industry, as well as State and local governments. During 1984, NASA will continue its efforts to help foster widespread dissemination of new technology developed by the Agency's programs.

4. *Space research and technology.*—The objective is to conduct the activities necessary to increase the efficiency and effectiveness of space systems and operations. The 1984 program provides for continuation of the research and technology base activities necessary for advances in the key discipline areas, and also continued progress in ongoing systems technology and experimental efforts.

5. *Aeronautical research and technology.*—The goal is to help preserve and strengthen long-term U.S. strength in aeronautical research and technology. Consistent with this goal, work will continue in 1984 on fundamental research in all basic aeronautical disciplines and the maintenance of related research facilities.

Activities will continue to provide a strong research and technology base in the aeronautical disciplines of aerodynamics, propulsion, avionics, and flight controls, human-vehicle interaction, materials, and structures; and to conduct generic technology activities relevant to the major classes of aeronautical vehicles such as subsonic aircraft, rotorcraft, and high performance aircraft.

In 1984, an important new effort will be the initiation of development of a numerical aerodynamic simulation capability in computational fluid dynamics which will provide new, powerful analytical techniques for the design of all types of future aerodynamic vehicles. Other new development efforts include an advanced composite structures technology and technology for next generation rotorcraft. In addition, ongoing major systems technology programs will be continued in rotorcraft and high-speed aircraft.

6. *Energy technology.*—In 1984, this program provides reimbursable support to Government agencies engaged in national energy programs.

7. *Supporting activities.*—This program provides tracking and data acquisition support to the entire NASA flight program, including automated missions, manned missions, sounding rockets, and aerodynamic test flights. Lease payments for the new Tracking and Data Relay Satellite System will continue in 1984.

CONSTRUCTION OF FACILITIES—Continued

This appropriation provides for the contractual services for the design, repair, major rehabilitation, and modification of facilities; the construction of new facilities; minor construction; the purchase of land and equipment related to construction and modification; and advanced design related to facilities planned for future authorization. The principal projects in the 1984 program are described below:

1. *Space transportation systems.*—This activity includes funds for Space Shuttle facilities at various locations.

2. *Scientific investigations in space.*—This activity includes the construction of a cargo hazardous service facility, and modifications to a spacecraft assembly and encapsulation facility for cargo processing at the John F. Kennedy Space Center, Fla.

5. *Aeronautical research and technology.*—This activity includes the construction of the fluid mechanics laboratory at the Ames Research Center, Moffett Field, Calif., and modifications and addition for the composite materials laboratory and modifications to the 30- by 60-foot wind tunnel at the Langley Research Center, Hampton, Va.; and modifications for small engine component testing facility and modifications to the icing research tunnel at the Lewis Research Center, Cleveland, Ohio.

7. *Supporting activity.*—The estimates for this activity include the construction of an aeronautical tracking facility at the Hugh L. Dryden Flight Research Facility, Edwards, Calif.; construction of a frequency standards laboratory and modifications to the space flight operations facility at the Jet Propulsion Laboratory, Pasadena, Calif.; and relocation of 26-meter STDN antenna, Spain; repair, rehabilitation and modification of facilities, not in excess of $500 thousand per project, and minor construction of new facilities and additions to existing facilities, not in excess of $250 thousand per project at various NASA installations and at Government-owned plants operated by contractors; and for facility planning and design.

90 00	Outlays, excluding pay raise supplemental				1,130,019	1,219,850	1,247,500
91 20	Outlays from civilian pay raise supplemental					30,150	

This appropriation provides for research in Government laboratories, management of programs, and other expenses for the operation of NASA installations.

Responsibility for the space transportation systems activity is located at the John F. Kennedy Space Center, Kennedy Space Center, Fla.; Lyndon B. Johnson Space Center, Houston, Tex.; Marshall Space Flight Center, Huntsville, Ala.; and the National Space Technology Laboratories, Bay St. Louis, Miss. The scientific investigations in space and space and terrestrial applications activities are concentrated principally at the Ames Research Center, Moffett Field, Calif.; Goddard Space Flight Center, Greenbelt, Md.; Langley Research Center, Hampton, Va.; Lewis Research Center, Cleveland, Ohio; Lyndon B. Johnson Space Center; Marshall Space Flight Center; and the National Space Technology Laboratories.

The space research and technology activity is conducted at the Ames, Goddard, Langley, Lewis, Johnson, and Marshall Centers.

Aeronautical research and technology work is conducted at the Ames, Langley, and Lewis Research Centers.

Programwide support and management are provided by NASA headquarters, Washington, D.C. Support activities for tracking and data acquisition requirements are performed at the Goddard Space Flight Center.

AMERICAN OPTIONS IN SPACE

IT HAS been a quarter-century since America put its first satellite into space and a decade since the last lunar expedition closed the era of flag-bearing astronauts *(see Space Events, p. 134)*. These exploits captured the public's imagination and ensured financial support for the U.S. space program through the 1960s. During the following decade, the National Aeronautics and Space Administration (NASA) scored remarkable successes with its unmanned probes of other planets, and it mapped plans for space travel in the 1980s as difficult and perhaps as exciting as the Man-on-the-Moon program that President Kennedy set in motion in 1961.

Motivated by the high cost of space travel, NASA searched for more efficient ways to exploit space and its resources. This fostered the idea of a Space Transportation System, or STS, for carrying cargoes ("payloads") into orbit and returning to Earth aboard a fleet of reusable space shuttles *(see illustrations, p. 133)*. Now after five successful flights of the space shuttle *Columbia*, the first flight of the new shuttle *Challenger* from the Kennedy Space Flight Center in Florida is scheduled for sometime in middle or late March — barring further delay that postponed the original launch date from Jan. 27 because of a fuel tank flaw. Though a setback, which is likely to postpone the launching of other flights this year, it does not dampen optimism in the space agency that the United States is on the verge of a commercial, scientific and military renaissance in space.

However, this view is not universally shared. The science community is complaining that space sciences are taking a back seat to the military applications of space. And as for America's attempt to push ahead with the commercialization of space, it is encountering competition from Russia, Europe and Japan. In recent years, all three have been developing inexpensive means of launching satellites, and at least Europe and Japan are trying to attract some of the international business — including American business — that NASA was counting on to support the commercial aspect of the Space Transportation System.

There is an ambitious schedule of shuttle flights, nevertheless. Sixty-three are planned through 1987. This September the

Columbia is due to carry aloft a $1 billion Spacelab developed by the European Space Agency[1] for NASA, enabling scientists to work in a "shirt-sleeve environment" — without bulky spacesuits and carry out experiments for research institutes, commercial customers and government agencies.

Then in March 1984, if the timetable holds firm, the new shuttle *Discovery* will make its first flight. It will carry a communications satellite and a facility for experimenting with the separation of chemical compounds that can best be performed where gravity is weak or virtually absent. This kind of "materials processing" will be studied further in April 1985 when the shuttle *Atlantis* is sent into orbit. This will be done in a Spacelab mission jointly sponsored by NASA and the West German goverment.

About one-third of the *Atlantis* payload capacity will be leased to private, commerical interests — unless opposition that has been reported in the White House materializes to block the plan. The trade magazine *Aviation Week & Space Technology* has reported that David A. Stockman, director of the presidential Office of Management and Budget, does not want federally funded space transportation to haul private cargoes unless the government realizes a profit from that activity.[2]

Selling Industry the Shuttle's Services

NASA is moving ahead despite any official misgivings, promoting its "Getaway Special." For fees up to $10,000, individuals and corporations can lease up to five cubic feet of space aboard a future shuttle flight, and place up to 200 pounds on board. So far about 500 customers have signed up to have their cargoes, usually involving scientific experiments, taken into orbit. The agency is also developing plans to take passengers into space late in this decade.

Business involvement in the U.S. space program is not new, of course. Since its inception, NASA has contracted with large companies for a variety of services and products. Private industry has supplied parts and developed entire systems for space projects. The prime contractor for the space shuttle orbiter, for instance, is Rockwell International's Space Division at Downey, Calif. Hundreds of other private companies are subcontractors. Now that the space shuttle is operational, the private sector of the economy is looking at it with wider interest.

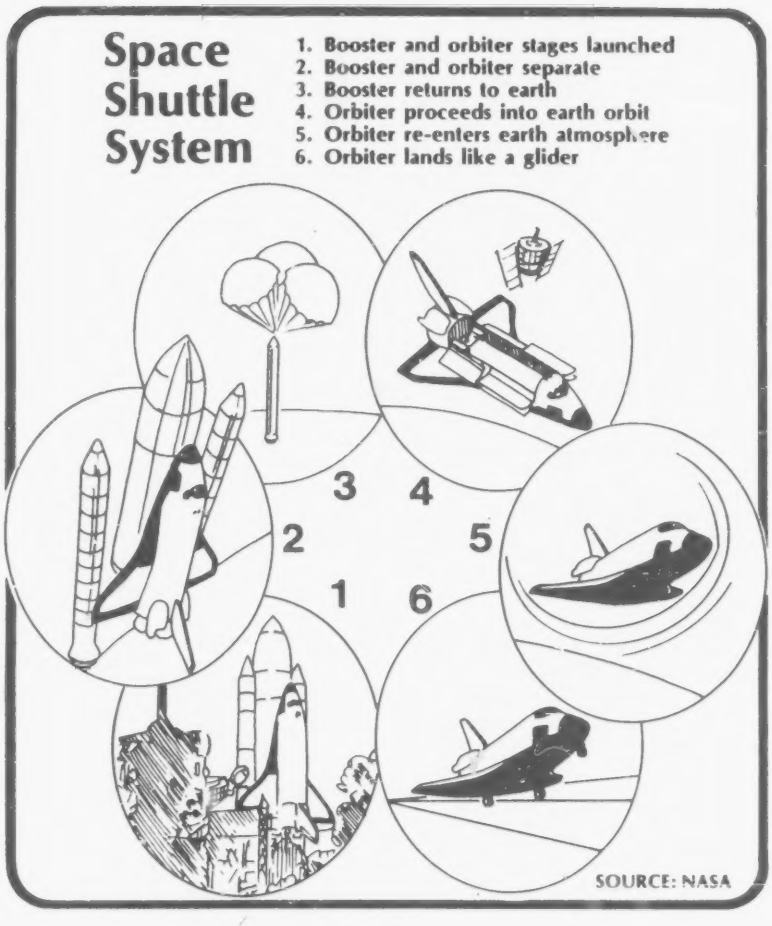
[2] *Aviation Week & Space Technology*, Oct. 25, 1982, p. 11.



Communications satellites were the shuttle's first commercial payload. Last November the *Columbia* carried into space and launched two $30 million satellites for Telsat Systems of Canada and Satellite Business Systems of McLean, Va. Each paid NASA $9 million for performing this service, enabling Telsat to beam television signals to rooftop antennas in Canada and SBS to operate a long-distance telephone system.

More than three years before that event, a NASA planner, Jesco von Puttakamer, predicted that communication satellites would constitute the shuttle's main payloads throughout the 1980s. "[U]sing the shuttle," he explained, it will be practical "to assemble much larger antennas and reflector structures than those we now have in orbit." [3] Even then, in 1979, commercial investments in satellites had exceeded $1 billion, von Putta-

Space Events, 1957-82

1957.	Russia launches first satellite Sputnik on Oct. 4.
1958.	U.S. sends up its first satellite, Explorer, Jan. 31.
1960.	Echo 1, first TV communications satellite in orbit.
1961.	Cosmonaut Yuri A. Gagarin becomes first human in orbit, April 12. President Kennedy calls May 26 for moon landing.
1962.	John Glenn becomes first American to orbit the Earth, Feb. 20. First successful interplanetary mission, Mariner 2 to Venus.
1963.	Soviets put first woman, Valentina Tereshkova, in space.
1965.	U.S. launches first 2-man mission, March 23. First space walk by cosmonaut Alexey Leonov. Early Bird, first commercial communications satellite, links U.S. and Europe.
1966.	Venera 3 lands on Venus, first man-made object to reach another planet.
1969.	U.S. lands first men on moon, July 16.
1971.	Russia's Salyut 1 becomes first space station in Earth's orbit.
1972.	President Nixon authorizes space shuttle, Jan. 5. Last Apollo mission, Dec. 7-19.
1973.	First Skylab crew launched May 26.
1974.	Skylab 4 crew aloft 84 days, a record. Mariner 10 conducts first probe of Mercury.
1975.	Apollo-Soyez projects links U.S.-Soviet crews in space, in July.
1981.	Space shuttle makes first of test flight, April 12.
1982.	Shuttle's first operational mission, Nov. 11.

kamer reported, predicting that the figure would be several times greater by the mid-1980s.

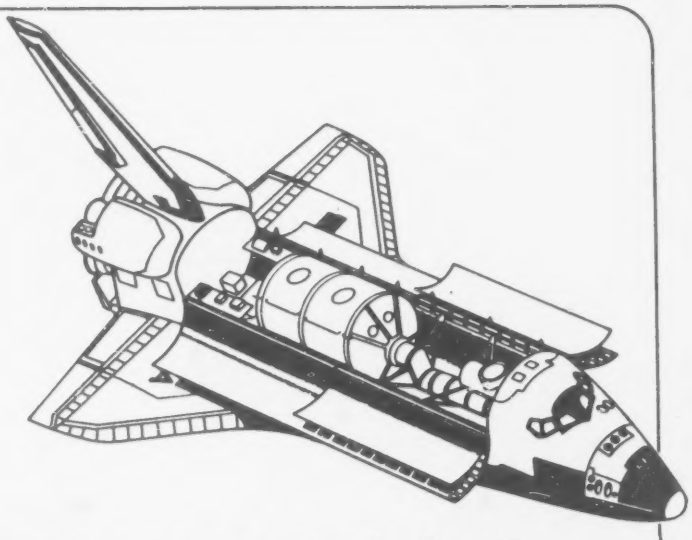
Communication satellites receive signals from a ground station and retransmit them over a very broad area, eliminating the need for telephone and telegraph lines, cables and other surface means of communication. American Telephone & Telegraph Co. put up the first working communication satellite, Telstar, on July 20, 1962, to transmit telephone calls and some television signals across the Atlantic Ocean. Though disabled the next year, Telestar was followed by a procession of others.

Commercial interest in satellites was so strong that in 1962 Congress authorized the creation of the Communication Satellite Corp. (Comsat), jointly controlled by private industry and the federal government.[4] Comsat arranged with NASA to launch scores of satellites for communications purposes. There also have been dozens of satellites for weather observations, navigation, traffic control, mapping and surveying.

Spawning the Communications Economy

Social forecaster John Naisitt makes the point that today's shuttle can orbit a 65,000-pound payload vastly greater than the

[4] See Congressional Quarterly's *Congress and the Nation*, Vol. I (1965), pp. 320, 326.



NASA's concept of shuttle carrying Spacelab into orbit

182-pound Sputnik, "and many, many times more sophisticated." In the past, the complex parts of a satellite system had to be in a ground station. "But the new shuttle . . . can launch larger satellites that incorporate ground station functions. . . ."

For all that "the space shuttle has a lot more to do with the globalized information economy than it will ever have to do — in our lifetimes — with space exploration." he added. "I do not want to minimize the importance of *Sputnik* and *Columbia* in opening up the heavens to us. But what has not been stressed enough is the way satellites transformed the Earth into what Marshall McLuhan called a global village."[8]

"No one looking at space a quarter century ago foresaw all ways in which space systems have altered human life," writes Daniel Deudney, a senior researcher with Worldwatch Institute, "and no one today predicting space activities over the next 50 to 100 years is likely to predict all the uses to which satellites will be put. Yet enough is known about the potential of space and the needs of earth that some ideas — large-scale space colonies, solar power satellites and asteroid mining — can be eliminated as practical and desirable goals. A modest industry producing

[8] John Naisbitt, *Megatrends*, Warner Books, 1982, pp. 12, 58. Naisbitt is publisher of the quarterly *Trend Report* and chairman of the Naisbitt Group, a research and consulting firm, in Washington, D.C. McLuhan, a Canadian professor-author, has been called the guru of the age of television. He is perhaps best known for his book *The Medium is the Massage* — or message.

certain high quality products is possible within this time horizon, but is unlikely to surpass the economic contribution of communications satellites."[6]

> The success of the satellite communications industry [Deudney added] has spawned a great deal of speculation about the possibility of building industries in space. Experiments aboard the U.S. *Skylab* in 1974 revealed that the weightless, airless conditions of space enabled the production of certain goods that are impossible to manufacture on Earth. Without gravity, crystals form much more regularly, permitting the creation of glasses and electrical devices that have vastly higher performance than any others. And the products can be formed without containers, eliminating impurities that are the major limit to the performance of certain optical and metallurgical products on Earth.[7]

The drug industry is expected to become one of the main users of weightless space. A Johnson & Johnson subsidiary is working with NASA to conduct an extensive research program. Jesco von Puttakamer, the NASA planner, estimates that space manufacturing could lower the production cost of a drug to prevent blood clots from $1,200 a dose to about $100.

Electrophoresus Operations in Space (EOS), a subsidiary of the McDonnell Douglas aerospace manufacturing company, is reported to be experimenting extensively with producing pharmaceuticals and other materials in space. An official of the company said it was investing "millions of dollars" in materials research to determine what products could benefit from production in space. The results so far show that "hundreds" of new or improved products could be produced there.

NASA has predicted that it will not have enough launch facilities to meet the demand once big businesses become actively engaged in space manufacturing. Some companies are reported to be considering ways of establishing their own space transportation systems and bypassing the shuttle. One company, Space Services Inc. of Houston, went a step further last September by launching a small spacecraft made of surplus parts and carrying a mock payload of 40 gallons of water. It soared to 52.9 miles and plunged into the Gulf of Mexico, 326 miles from the Matagorda Island launch site in Texas. The test was part of the company's plan eventually to sell "low-cost, market-oriented" space services to customers, according to David H. Hannah Jr., the company chairman.[8]

The main problem facing a company that wants to go into

[8] Quoted in *The New York Times*, Sept. 10, 1982

space transportation is finding a competitive alternative to NASA's shuttle. It conceivably could purchase boosters that the space agency no longer uses. Possibly a well-financed company could build its own shuttle, or buy one of NASA's — as the Space Transportation Co. of Princeton, N.J., has been attempting to do for an offering price reported to be about $1 billion.

Fairchiid Industries at Germantown, Md., is spending more than $100 million to study the feasibility of building a series of "spacecraft buses," a company official said. Each "bus" would be launched into low orbit by NASA's space shuttle and then use onboard propulsion to move into higher orbit. Fairchild envisions leasing all or some of its "buses" to other companies.

While large companies such as Fairchild and McDonnell Douglas may need no further encouragement to invest in space research, many smaller ones remain skeptical that such ventures will be profitable. NASA's Customer Services office is developing pricing policies to persuade them to become shuttle users. However, the U.S. General Accounting Office has recommended to Congress that NASA charge more for use of the shuttle and gradually abandon its low-pricing policy.[9] NASA is technically a research and development agency and thus is not supposed to market its activities. This fact has led the agency to consider handing its shuttle operations over to a private company. NASA Administrator James M. Beggs is expected to make a decision this year on such a transfer.

Rising Competition in Europe and Japan

As the United States tries to find the right combination of government and industry involvement in the commercialization of space, several foreign countries are swiftly becoming competitive. The congressional Office of Technology Assessment recently advised the lawmakers that "increased foreign competition and stringent fiscal restraints" in the United States could diminish the U.S. lead in satellite communications, land-remote sensing, transportation and materials processing in space.[10]

Phil Culbertson, NASA associate deputy administrator, has said that the Japanese "have made major inroads in communications technology, and the Europeans are now vigorously marketing a launch system." [11] The European Space Agency's three-stage launch rocket, *Ariane*, already has lured commercial users away from the U.S. shuttle.[12] *Ariane's* American customers include Western Union, which has booked

its Westar satellite for launching this year, and Southern Pacific Communications of California. But unlike the shuttle, the unmanned Ariane cannot retrieve satellites or carry astronauts aboard to repair and replace damaged satellites.

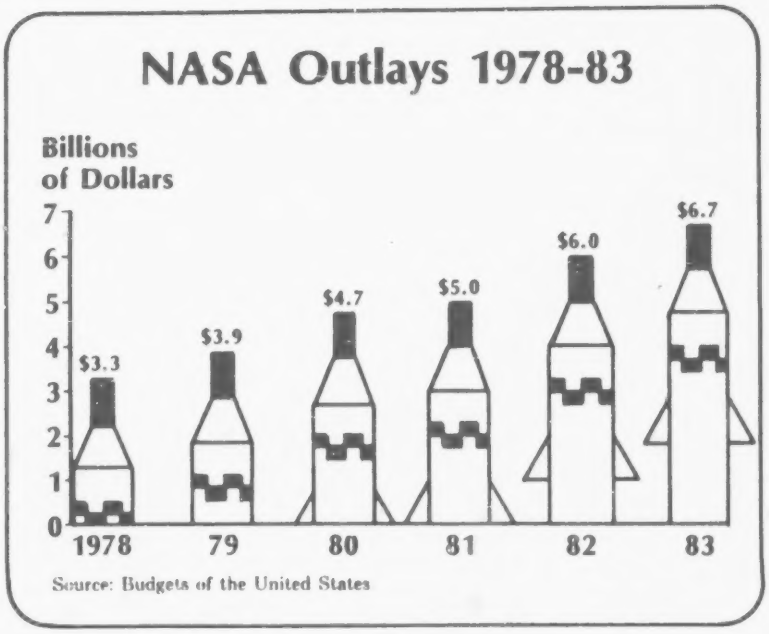
Militarization of Space

WHILE the United States was developing the space shuttle, the Soviet Union was creating and launching *Salyut* space stations. The first one, in 1971, and subsequent ones in 1972, 1973, 1975 and 1977 have been characterized by James E. Oberg, a Soviet affairs specialist at NASA, as of the "civilian" variety. But he said others that were launched in 1973, 1974 and 1976 were essentially for military purposes.[13] However, it is often difficult to separate military purposes from the scientific—since any number of scientific advances in space can be adapted to military uses.

It is no secret that both the United States and Russia eye each other's space efforts warily, and often accuse the other of being obsessed with the military applications of space technology. According to the Department of Defense, the Soviet Union spends about 70 percent of its space budget on military-oriented missions, and an additional 15 percent on combined military and civilian activities.[14] About 20 percent of NASA's $6.6 billion budget in this fiscal year is allocated to military missions. However, there is an additional $8.3 billion in the Defense budget for military space activities, bringing America's military share of its total $14.9 billion space budget close to 70 percent also.

"Space in military terms is big, important business and getting more so," *Air Force Magazine* observed last summer.[15] Among the military services, the Air Force gets the lion's share of space money, some $7.2 billion in this fiscal year's budget, amounting to 9 percent of the Air Force's spending. The Air Force plans to use the space shuttle as a launching pad for spy satellites and for satellite service, repair and modification. Eventually it would like to use the shuttle as a base for assembling a manned space station which, among other things, could launch spacecraft to higher orbits for longer duration.

[13] See Oberg's book, *Red Star in Orbit* (1981).
[14] See "Soviet Military Power," publication released by the Public Correspondence Division, Office of Assistant Secretary of Defense for Public Affairs, 1982.
[15] *Air Force Magazine*, August 1982, p. 49. The magazine, published by the Air Force Association, does not officially speak for the Air Force but usually reflects its views.



Of the 234 shuttle flights scheduled through 1994, according to the General Accounting Office, 114 (48 percent) are military related; 13 of the initial 44 flights through 1986 are specifically military. NASA officials say that most of the shuttle's current military missions are "passive" — they involve such things as weather predictions, surveillance (spy satellites), navigation and communications. But the shuttle also is equipped to launch satellites that would give early warning of missile attacks, and would provide advanced and improved navigation for warships, warplanes and military vehicles.

Fear of Soviets Holding 'High Ground'

While "militarization of space" has been decried in Congress and in the press, Defense officials argue that the alternative is to let Russia gain uncontested control of "the high ground" and thus threaten U.S. security. They point to Soviet cosmonauts repeatedly setting records for length of time in orbit, currently up to 211 consecutive days, and note that Russia launches more satellites than the United States does. In June 1982, the Soviets established a new record by placing 15 satellites in orbit, about the same number this country launched in all of 1981. During that entire year, according to U.S. calculations, the Russians launched 858 military and 392 civilian satellites.

Some of the satellites conduct routine military tasks such as communications, mapping and reconnaissance. Like other nations with satellites in orbit, they are used to monitor world grain crops. Other satellites are more worrisome. U.S. sources

say the Soviets have flown and tested about 20 "killer" satellites, designed to track down and destroy enemy satellites, spaceships and space stations. The Russians reportedly are also testing "space mines" — killer satellites which would orbit the Earth for long periods of time, awaiting detonation by ground command, for purposes as yet unknown. A Department of Defense spokesman said at least one Soviet killer satellite circles the Earth in a low orbit.

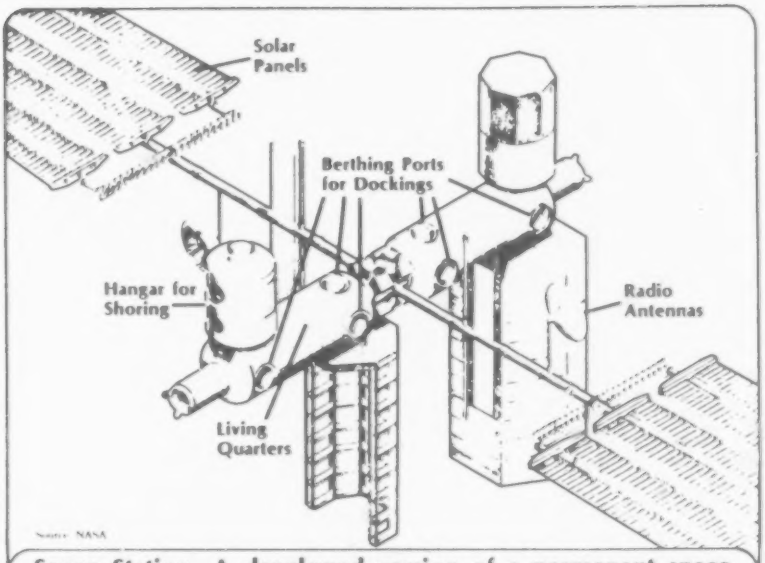
Like their American counterparts in the shuttle, Soviet cosmonauts use their Salyut space stations to conduct "civilian" experiments — the manufacture of special materials, seed growth in zero gravity, and an assortment of scientific activities. But it's the secret, military missions of the Soviet space program that worry U.S. officials. Richard D. DeLauer, Undersecretary of Defense for research and engineering, told a Senate Foreign Relations subcommittee last fall that the Salyut program "engages in military activities and may be the forerunner of a weapons platform."[18]

There is disagreement among experts whether Russia is ahead or behind the United States in its space activity. The Soviet program presumably does not have a reusable craft such as the U.S. shuttle — but that is not certain. There is some belief that, although unadvertised, a reusable Soviet space vehicle is being developed. As for Russia having more satellite launchings, that may reveal weakness rather than strength. The Soviet satellites usually do not remain operational as long as American satellites, so more of them must be put into orbit.

Nevertheless, Soviet space operations have been impressive to many. Oberg, for instance, believes Russia is developing the Salyut as a small basic space station in order to acquire long-term experience in space operations. Already, Soviet cosmonauts have spent more than twice as much time in orbit than have American astronauts. Valeriy Ryumin, the most experienced civilian engineer-cosmonaut, accumulated 362 days of space flight on three missions in 1977, 1979 and 1980.

While U.S. experts predict the Russians will continue to use expendable boosters and capsules in the near future, it is likely that at the same time they are developing a permanent space station to be manned by three or four cosmonauts for as long as a year at a time. It is envisioned that later in the 1980s or in the 1990s, Soviet space stations would be able to accommodate up to six crewmen. Boris Petrov, chairman of the Soviet Interkosmos Council, has been quoted as saying "scientists are already busy designing large stations for a crew of 12 to 20, with

[18] Testimony before the Subcommittee on Arms Control, Oceans, International Operations and Environment, Sept. 20, 1982.



Space Station. A developed version of a permanent space station. Included is a scientific space laboratory, a materials-processing factory, a module for servicing payloads and another for fabrication of large space systems.

a life span of up to 10 years, which would replace the present small stations."[17] Soviet scientists also have predicted the appearance of "space towns" by the end of the century.

Permanent Bases Aloft; Killer Satellites

American space buffs, too, are enthusiastic about the idea of a space station. NASA Administrator Beggs has called a manned space station "the next logical step" after the development of the shuttle. He envisions it as the assembly point for manned and unmanned missions to Mars and other planets.[18] The space agency has contracted with eight aerospace companies[19] to study the potential commercial, military and scientific uses of a space station. The study results are expected in April.

Although President Reagan issued a national space policy statement last July 4, he stopped short of backing a big new project, such as a manned space station. His statement instead included a general endorsement of the space program and a commitment to the use of space for commercial and national security purposes. Reagan set out a number of civilian objec-

International Law and Outer Space

The main international agreement governing outer space was drafted in 1967 by a U.N. body and is known today as the Outer Space Treaty. It has been signed by 107 countries, including all that are active in space.

A second U.N.-sponsored space agreement, known as the Moon Treaty, was drafted in 1979 but has been ratified by only three countries, of which only one (France) has a space program. The 1967 treaty holds that outer space is not subject to national appropriation while the later one goes a step further, saying that the moon and other celestial bodies are the "common heritage of mankind" — a concept promoted by Third World countries but resisted by both the industrial West and Russia.

tives, including research and experimentation in the origin and evolution of the universe and solar system, the Earth's environment and its relation to the sun, and the technology of permanent space facilities. He also called for "a climate conductive to expanded private sector investment and involvement in space activities."

For national security aspects of space, the policy stated that the United States will proceed with development of an anti-satellite capability to deter threats to U.S. space systems. The statement added that the United States would develop an attack warning, notification and verification capability to detect and react to threats to the United States in space. A Fact Sheet issued by the White House describing the policy noted that it grew out of a National Security Council study, which explains its emphasis on defense issues, analysts said.

Scarcely more than a month after Reagan issued his policy statement emphasizing military aspects of space, the secretary general of the United Nations, Javier Perez de Cuellar, opened a U.N.-sponsored conference in Vienna on the future of outer space by warning that an arms race in space holds the "potential for confrontation."[20]

Russia and the United States negotiated off and on during the 1970s to control anti-satellite weapons, but the talks broke off at the end of the decade when Russia invaded Afghanistan. One immense barrier to agreement was Russia's insistence that the space shuttle be considered an anti-satellite system since it had the capability of intercepting and destroying Soviet satellites. The United States argued that shuttles are too expensive ever to become numerous[21] and, moreover, are not feasible anti-satellite weapons.

[20] Statement to the Unispace '82 Conference, Second United Nations Conference on the Exploration and Peaceful Uses of Outer Space, Aug. 9, 1982.

[21] Costs run to about $1 billion apiece; the United States currently expects to build only four.

American Options in Space

Both the United States and Russia are known to be trying to build an even more futuristic weapon using laser beams. As envisioned, powerful lasers in orbit would intercept and destroy intercontinental ballistics missiles in flight as they arc above the Earth. However, it has been estimated that a laser ray system capable of providing the United States protection from Soviet ICBMs might cost $1 trillion or more. There is an even greater drawback. "Using space-based lasers as a ballistic missile defense suffers from the same problems — in spades — that led the U.S. and U.S.S.R. to agree by treaty to abandon all anti-ballistic missiles a decade ago," Daniel Deudney writes. "The central problem of all anti-ballistic missile systems is the ease with which the highly sensitive radars that track oncoming missiles can be utterly blinded."[33]

The American public appears about evenly divided on whether the U.S. space program should focus primarily on national defense or scientific exploration. In an NBC/Associated Press poll conducted in 1981, 47 percent of the people questioned favored a military emphasis while 43 percent said scientific aspects should be emphasized. The remaining 10 percent wanted an equal emphasis on both.

Directions of Space Science

MILITARY and commercial endeavors in space are possible only because gigantic strides have been made in space science and technology during the past quarter-century. Space science can be divided into two types: that which looks inward for a better understanding of our own planet and that which looks outward for a better understanding of the universe. A comparison of the NASA Space Science Program budgets in 1965 and 1983 indicates that today outer space is taking a back seat to the shuttle and Earth satellite programs. The 1983 figure is $697.8 million, less than half of the 1965 outlay in terms of constant dollars — without the effects of inflation. NASA's planetary missions make up only about 5 percent of the space agency's current budget.

The commitment to the shuttle and Earth satellites has led to the cancellation of postponement of several scientific projects. NASA's Office of Space Science has only two major missions in this decade, putting the Space Telescope *(see p. 146)* in orbit and sending another spacecraft to Jupiter. In contrast, there were 24 missions in the 1970s. NASA also postponed to 1987-88

[33] Daniel Deudney, *op. cit.*, p. 25.

Nuclear-Powered Satellites

Since a nuclear reactor can generate much more power for a satellite than the usual array of solar panels, they are favored for "supersatellites" of the future — especially for military purposes. Already the United States has one aloft and Russia has launched 18. One was Cosmos 1402, which plunged into the Indian Ocean Jan. 23 — except for fiery fragments of final piece which came down in the South Atlantic Feb. 7. They landed far from human habitation but caused concern over a cloud of radioactive dust the satellite's reaction left in the upper atmosphere.

Another nuclear-powered Cosmos crashed into a remote area of northern Canada in 1978. In that case the reactor's uranium fuel burned up high in the atmosphere and apparently spared the impact area of radioactive contamination. American space officials say that Russia has put up 18 nuclear-powered satellites during the past several years. The United States launched one such satellite in 1965 which is still operating in orbit. Defense officials are reported to be considering adding others.

a Gamma Ray Observatory to help astronomers study the universe at very high frequencies. The project Venus Orbiting Imaging Radar, which would study the cloud-covered Venusian surface in detail, also has been delayed.

Carl Sagan, the astronomer-author, has said that future knowledge of "deep" space is being denied by present-day cancellations and postponements. "We are the beneficiaries of decisions made in the 1960s and the 1970s," he said. "There are no new starts in this decade, with the single exception of Galileo . . . and that worries me greatly."[33]

American scientists are especially upset that NASA has decided not to sponsor a space probe to enter and investigate the great swath of ice, frozen gases and other celestial debris that make up Halley's Comet when it reappears in the Earth's view in the winter of 1985-86. The Office of Technology has said that the space agency's lack of interest in a comet mission "puts U.S. scientists at a clear disadvantage with respect to the Europeans and the Soviets, both of whom will be flying such missions." Sagan has said: "There is the ominous and very real prospect that American leadership in planetary exploration will come to an abrupt end."[34]

Reflecting the rising interest in Halley's Comet, the Library of Congress recently published a listing of books and articles that already have appeared on the subject. The listing run to seven printed pages. There is even a *Halley's Comet Watch*

[33] Remarks in an interview broadcast on "The MacNeil-Lehrer Report," PBS-TV, Nov. 4, 1981.
[34] Quoted in *The New York Times*, July 19, 1981.

Newsletter.[25] The comet's sighting occurs every 75 years when it approaches the sun on its journey back from the outer reaches of our solar system. The Soviet Union, in partnership with France, is sending out two spacecraft, the Venera Halley 1 and 2, to witness the event at close range.

In December 1984 the spacecraft should come within 6,000 miles of the comet's solid nucleus and spend hours taking pictures and gathering data. In July 1985 the European Space Agency will launch the Giotto, which will fly within 100 miles of the comet. A Japanese spacecraft, the Planet A, will be launched the following month on the same mission.

Past Leadership in Planetary Research

The U.S. space program has long been the pioneer in scientific ventures. There have been dozens of unmanned exploratory probes over the years. In 1959, the Mariner 1 and 2 spacecraft circled Venus. The Pioneer series continued the space quest among the planets in the 1960s and 1970s. Pioneer 10 and 11, launched in 1972 and 1973, were the first spacecraft to visit Jupiter. Pioneer 11 went on to Saturn and in September 1979 returned the first close-up images of that planet.

Since 1979, the Pioneer Venus Orbiter has been circling Venus, studying its atmosphere, taking hundreds of ultraviolet pictures and radar-mapping its surface. Five Pioneer Venus probes have descended by parachute through the planet's atmosphere, sending data back to Earth for over an hour. From that information scientists confirmed their suspicion that Venus is a "hellish" planet, with a surface temperature about 900 degrees Fahrenheit, hot enough to melt lead. Pioneer Venus Orbiter will continue to operate through 1985, changing orbital paths.[26] Pioneer spacecraft operations and data analysis activities were terminated in September 1983, although limited operations necessary to the survival of the spacecraft were performed. In October 1986, Pioneer will become the first space probe to leave to solar system and travel into eternity.

Voyager 2, following its sister ship Voyager 1 to Saturn by a different trajectory, discovered in a region surrounding Saturn the hottest gas yet detected in the solar system. Voyager's instruments showed temperatures ranging from 600 million to

---

[25] The listing appears in the *LC* [Library of Congress] *Information Bulletin*, Nov. 26, 1982, compiled by Ruth S. Freitag of the Library's Science and Technology Division. The newsletter describes itself as the "official publication of Halley's Comet Watch '86 . . . an international organization dedicated to the historical, scientific study of . . . Halley's Comet." Its address is Box 188, Vincetown, N.J. 08088.

[26] The Soviet Union also has sent probes to Venus. On Feb. 28 and March 5, 1982, two Soviet spacecraft landed on Venus, the seventh and eighth the Russians have landed on the planet.

more than one billion degrees Fahrenheit, about 330 degrees hotter than the Sun's corona. Like Voyager 1, Voyager 2 concentrated on Saturn's rings, but the spacecraft also studied Saturn's moons. It is now destined to reach Uranus in 1986 and Neptune in 1989 unless NASA decides to cancel those two visits.

NASA, in cooperation with West Germany, will launch the survey spacecraft Galileo toward Jupiter in 1985. Galileo initially was scheduled to go into orbit around Jupiter in 1987, but budget austerity will slow its flight. It won't reach the planet until 1989. A conventional upper-stage engine will be used to fire the spacecraft instead of the new, more powerful, hydrogen-fueled, high-energy Centaur engine, which would have enabled Galileo to fly a more direct path to Jupiter.

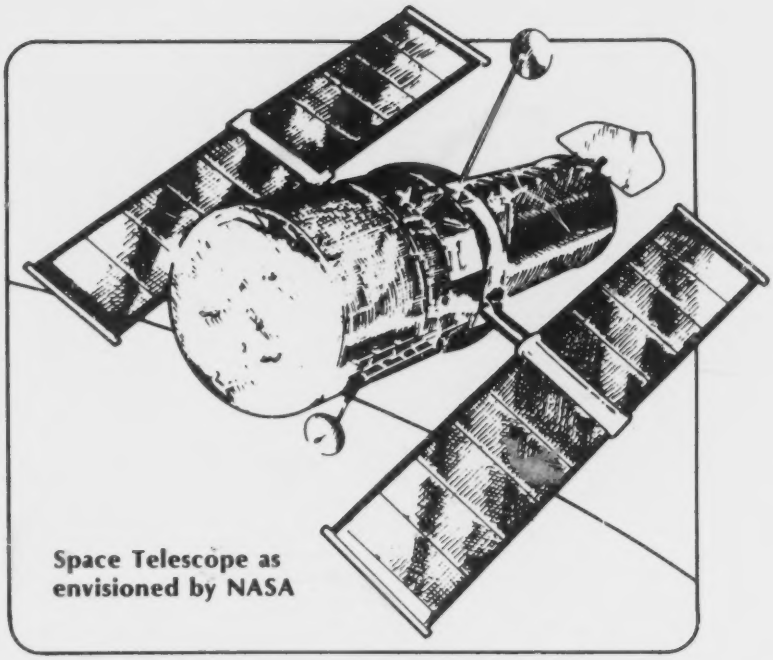
Telescope in Orbit and Earth Projects

Mankind will be able to peer farther into space than ever before when a gigantic telescope is sent above the Earth's atmosphere aboard a space shuttle and then placed in orbit. This log-shaped Space Telescope, 43 feet long and 14 feet wide and weighing 12 tons *(see illustration)*, is expected to remain operable well into the 21st century. With a view unhindered by the Earth's atmosphere, astronomers expect to see stars created 14 billions years ago, about the time of the creation of the universe, according to some scientific thinking.

The telescope's first important assignment will include observations of Uranus to help plan the course of the Voyager 2 flyby of Uranus in January 1986. The telescope will also help astronomers study Halley's comet, though from a greater distance that the European and Japanese probes. Some scientists predict that one of the first discoveries with the telescope will be that of another planetary system.

For all of the fascination with planets and other celestial bodies, the space program's focus these days is essentially upon the Earth and its immediate surroundings. A decade ago on July 23, 1972, NASA inaugurated its Landsat satellite program to collect information about Earth's resources by means of remote sensing instruments placed on a platform in space. The Landsat 1 satellite was followed by 2 in 1975 and 3 in 1978, both of which are still in service. Last July 16, NASA launched Landsat 4, equipped with high advanced scanning devices that provide greater clarity of detail.

The space agency plans soon to hook a device called SARSAT — Satellite-aided Search and Rescue System — onto a satellite so that distress signals from ships and aircraft radio beacons can be monitored. The monitoring will be conducted by the National Oceanic and Atmospheric Administration.



Space Telescope as envisioned by NASA

One futuristic concept on the drawing board is a space solar-power satellite. It would collect solar energy and beam it to Earth for conversion into electricity. But as-yet-unsolved technical problems and cost estimates that range between $1.5 trillion and $3 trillion have led the National Academy of Sciences to recommend that no funding be allocated to the satellite's development until the 21st century.

Envisioning 21st Century Space Colonies

By then, according to some of the more visionary notions of what lies ahead, may come mankind's first feeble efforts to establish colonies in space — until now only the stuff of science fiction. By the early 1970s Princeton University physicist Gerard O'Neill was seriously proposing that the world embark on a plan to place facilities in orbit capable of sustaining life for 10,000 — eventually one million — people. As portrayed in his 1977 book *The High Frontier: Human Colonies in Space*, these would be idyllic, spacious settings covered by transparent domes.

There are other scenarios which today seem far-fetched if no absurd. Yet considering how many of Jules Verne's 19th century insights became reality in the 20th century, people living in the last quarter of this century dare not scoff at predictions of what the next may bring. More than artistic achievement may account for the moviegoing popularity of "ET" and the readership of Arthur Clarke's *2010: Odyssey Two.*

Why Billions Can and Should Be Spent on Space

By PAUL W. KEATON
Los Alamos National Laboratory

Over the next twenty-two years GNP will total about $100 trillion, easily supporting $130 billion for large focused space programs

Reproduced from Keaton, Paul W. Why billions can and should be spent on space. Astronautics & aeronautics, v. 21, May 1983: 86-88, 90-92 with permission of the copyright holder Aerospace America.

PAUL W. KEATON, (M), of the Los Alamos National Laboratory, conducts technology assessments in its office of planning and analysis. He joined Los Alamos in 1965 as a research scientist in nuclear physics. In 1972, he was a visiting scientist at the European Center for Nuclear Research in Geneva, and returned the following year to direct the Electronics Div. In 1980 he was appointed to a Pentagon study group evaluating U.S. nuclear weapons. Keaton received a Ph.D from the Johns Hopkins Univ.

"If we could first know where we are and whither we are tending we could then better judge what to do and how to do it." Abraham Lincoln[1]

Over the past 22 years the United States produced more income than in all of its previous history. The cumulative gross national product (GNP) from 1960 through 1981 was $52.7 trillion in constant 1982 dollars. The federal government spent 0.51% of that amount on our space program.

As a national investment, these expenditures on space can be considered successful. We depend increasingly on space for vital public services such as surveillance for treaty verification, remote sensing for finding resources, navigation for ships at sea, and weather reporting for nations around the world. In addition, members of the private sector are searching for more revenue-generating products and services in space similar to the lucrative communications-satellite business.

However, our national space program is undergoing a kind of "identity crisis" as the Shuttle goes into operation. This is similar to the post-Apollo slump suffered by NASA in the early 1970s before the inception of the Shuttle program. Having experienced this problem twice, should we not look ahead and seek long-range commitments for our space program?

Long-range commitments need not mean large financial outlays. The annual budgets can be any size so long as our society can afford them. To take a conservative approach, we may assume that the U.S. can "afford" to spend money on space activities as long as the per capita income is increasing. As it happens, that assumption does not represent a restriction on the analysis presented here.

To make practical long-range plans in either the public or private sector, we need to ask what kind of financial resources can be expected from the government and over what period of time. That is the purpose of this article.

U.S. Economic Trends: What has been the trend of the U.S. economy over the last century? F-1 shows our GNP in constant 1982 dollars from 1890 through 1981. (The numbers are taken from U.S. Dept. of Commerce publications.[2,3] The GNP implicit price deflator for 1982 is derived from an Office of Management and Budget publication.[4])

The most striking feature of the GNP since 1890 is its close fit to a single exponentially rising function,

depicted in F-1 as a solid curve. The least-squares fit to the actual constant dollar "data points" indicates that the average annual real growth rate of the GNP has persisted at 3.18% per year *despite all of the globally and nationally significant events that have taken place since 1890.* Diverse events having major political and economic consequences for the U.S. over the 92-year period include—

—The Great Depression of the 1930s.

—World War I and World War II.

—The advent of the New Deal in the 1930s (this included the abolishment of the gold standard in 1933, the establishment of Social Security in 1935, and the subsequent adoption of a mixed economy in which both public and private institutions exercise economic controls).

—Conversion of our nation's primary energy base from wood and coal to oil and natural gas (this was accompanied by the revolution of our transportation system from the horse and buggy to the automobile as well as the invention and commercialization of the airplane).

—Invention of the transistor, the integrated circuit, and the microprocessor.

—Invention and development of the liquid-fueled rocket engine used in the Apollo project to place men on the Moon in 1969 and subsequent technology spin-off.

—Assassination of President McKinley in 1901 and President Kennedy in 1963 and the resignation of President Nixon in 1974 under the threat of impeachment.

—Admission of 12 new states to the Union.

—The consolidated actions of the OPEC nations in 1973 that abruptly raised the price of oil.

—Emergence of the U.S. as a superpower with about one-twentieth of the world's population producing over one-fifth of the world's wealth.

Not one of these momentous events has left a distinguishable permanent imprint on the real growth rate of the GNP over the last 90 years! Rather, the effects of various events and developments have been compounded in such a way as to produce, on the average, a steadily increasing national income. This testifies to a certain robustness of our economy, whatever the explanation.

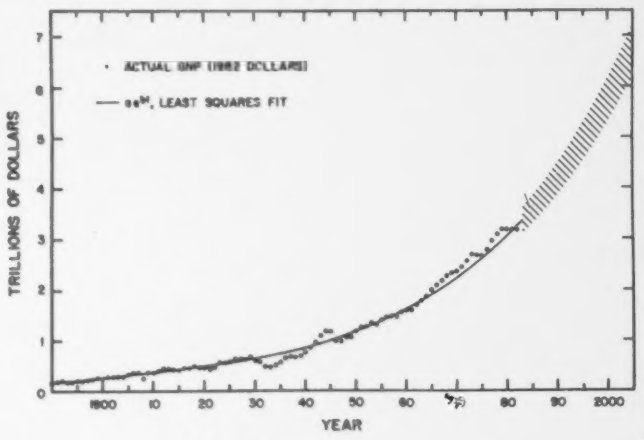
The exponential function of F-1 exhibits a "doubling time" of 21.8 years. (That is, $e^{bT} = 2$ for $T = \ln 2/b = 21.8$ years.) For instance, the 1959 GNP was $1,509 billion (in constant 1982 dollars) and it had slightly more than doubled to $3,153 billion 22 years later in 1981. This means that the total real income of the nation roughly doubled every generation, while the population increased by less than

T-1 CUMULATIVE U.S. GNP
Figures in billions of 1982 dollars

Beginning year (22-year interval)	Ideal[a]	Actual	Difference, b %
1894	$6,183	$6,673	7.9
1916	$12,444	$11,499	−7.6
1938	$25,045	$24,496	−2.2
1960	$50,406	$52,730	4.6
1982	$101,449	— —	— —

[a] Derived from exponential curve of F-1.
[b] Actual GNP minus ideal GNP divided by ideal GNP.

F-1 U.S. GROSS NATIONAL PRODUCT HISTORY
GNP since 1890 in constant 1982 dollars appear as dots. The line is an exponential fit with $A = 1.392 \times 10^{-34}$ dollars, $B = 0.0317$/yr, and t is in years A.S.

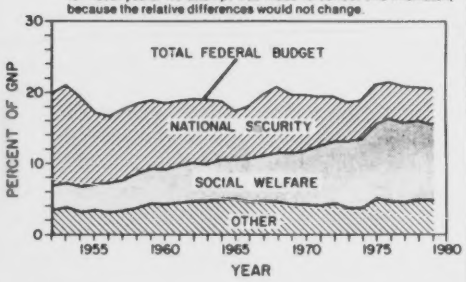


30%. One doubling time can be adopted as a natural unit of time for a "long range outlook" pertaining to U.S. economic perspectives.

Obviously the total GNP generated during any doubling-time period exceeds the cumulative GNP before that period. T-1 shows this actual accumulated GNP in constant dollars for four consecutive 22-year periods spanning 1894 to 1982 in an approximate ratio of 1:2:4:8. It also shows what the ideal cumulative GNP would have been, as calculated from the exponential curve of F-1.

For each of the consecutive 22-year doubling periods since 1894, the actual cumulative GNP varied from the ideal GNP by no more than plus or minus 8%. In addition, the ideal cumulative GNP for the next 22 years, starting in 1982, comes to

F-2 FEDERAL EXPENDITURES
Federal budget distributions as a percent of GNP since 1960. The GNP is given for the calendar year and federal budgets are given for fiscal years. No attempt was made to correct this mismatch, because the relative differences would not change.



$101,449 billion. It is adequate for present purposes to deal in round numbers and assume during the 1982-2004 period the U.S. will generate a GNP of $100,000 billion, plus or minus 8%, in 1982 dollars.

Federal Budget Trends: All U.S. space expenditures, like other government programs, are under constant and conflicting pressures from segments of the public, the military agencies, the private sector, the scientific and engineering communities, and political coalitions. Assume that space-program supporters will continue to fight for, and receive, the same fraction of their category of funding sources as they have fought for, and received, in the past. For our purposes, those funding sources must be identified in categories that are sufficiently narrow to distinguish among past budget trends and sufficiently broad to allow room for the statistical "give and take" of the budget process averaged over many years and several political regimes. To do this, we observe that space activities have been funded for the last 25 years mainly by NASA and DOD, and we identify the pools of federal money which supply their funds.

The federal budget constitutes less than 25% of our GNP. F-2 shows the 27-year distributions of federal-government spending as separated into categories of national security, social welfare, and "other."[2,3] These categories can be traced through the documents of the U.S. Dept. of Commerce. The sources of NASA funds are the "other" category, which has remained more or less a constant fraction of GNP, as shown in F-2. DOD spending on space comes out of the "national security" category, which has remained roughly constant over the last 20 years, since it has fallen by almost half as a fraction of GNP while the GNP itself has almost doubled. We can use these two trends—constant dollar and constant fraction of GNP—as guidelines to extrapolate government expenditures on space activities into the future. But first we need to ask how *far* into the future present trends can be expected to last.

How Long Will Present Trends Continue?: We can think of the GNP as the sum of a large exponentially rising component ae^{bt}, with a characteristic time of $1/b$, and a small modifying term that takes into account major events such as a worldwide depression or a world war. The average growth rate is then the sum of a statistically significant number of random and uncorrelated events, $b_i(t)$, such as the invention of the transistor (positive) and the influx of Japanese cars to the U.S. market (negative). The growth rate may be written $b=\Sigma_{i=1}^{n} b_i(t)$, for which the least squares search shows that, on the average b has been a constant over the last 90 years even though the components $b_i(t)$ have not been constant. It follows by analogy with physical systems that b cannot change rapidly over a period of time $1/b=31$ years. The validity of this reasoning for social systems is supported by the slow progress which results from major efforts to change population growth rates.

It is easy to show that if the average GNP growth rate changes slowly over 31 years, then the cumulative GNP is relatively insensitive to the growth rate changes. For example, we can represent b by a linear expression of time and show that a plus or minus 100% change in b over 31 years will cause less than a $\pm 10\%$ change in the cumulative GNP over the next 22 years. It is interesting that a 1982 projection of Data Resources Institute shows a U.S. GNP growth rate of 2.2-3.2% from 1982 to 1995. A recent Chase Econometrics study indicates a range of 2.4-3.5% in growth rates for the 1980s, and in 1979, the Townsend-Greenspan economic consulting firm gave 3.4% as the top of the range for

our nation's GNP growth rate in the 1980s.[5] It seems, then, diverse approaches, including the present one, are consistent with a U.S. GNP growth rate in the neighborhood of 3%. Once that rate is accepted as reasonable, our analysis is insensitive to slow variations from 3% in the future.

Short of catastrophic or disruptive events greater in magnitude than *anything occurring in the world during the last century,* the economic system possesses a certain "inertia." The empirical evidence in F-1, showing a persistent growth for almost a century, should cause us to be skeptical of any theory which predicts that the economy will do otherwise during the next doubling period.

The so-called "Limits to Growth" debate is a case in point.[6] W.W. Rostow has studied this matter as part of his thorough analysis of economic history on a grand scale.[7] He saw the extreme pessimism of the mid-1970s in the context of at least four similar periods in the last 190 years: 1790 to 1815, 1848 to 1873, 1896 to 1920, and 1936 to 1951. The last two periods occur within the time-span of F-1. Each time, the pessimism could be correlated with scarcity in a world business long-cycle. Rostow attempts to explain prices, interest rates, wages, income distributions, and investment patterns for each business cycle in terms of two major variables: the relative abundance or scarcity of various foodstuffs and raw materials, and the character of leading sectors in the major economies. Rostow draws the conclusion that each period of scarcity is accompanied by the coming of new supplies or development of new technologies.

How the nation copes with the present period of scarcity will affect our government's commitment to space programs in the next century. A society develops according to its expectations of the future. Those who view the future as a clash of the Third World's rising hopes with the Earth's scarcity of resources advocate no growth. Those who view the future as a challenge to our innovative and creative abilities advocate *growth* to increase the wealth of the world and *technology* to escape the limits to growth. In the past the latter view has always prevailed and turned out to be correct for our country.

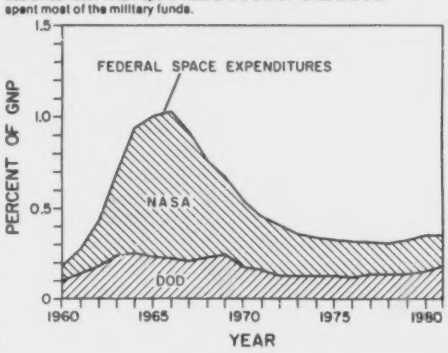
If this continues, before long we may need the extraterrestrial environment to develop both resources and manufacturing techniques.

From this perspective, and based on the historical precedence of four similar situations, it is likely that the American people will again choose the "growth scenario." But even if not, our economy is a going concern and the rate of growth can be expected to decline only slowly over three decades. As an extreme case, if we assume that the growth rate falls from 3% to 2% during the next decade, from 2% to 1% during the decade following that, and from 1% to 0% during the decade following that, the cumulative GNP between now and 2004 will be $90 trillion during the next 22 years. Based on today's population growth rate, it will still represent an increase of real per capita income for our country.

In other words, present trends are expected to change only slowly over the next three decades, and the U.S. can afford to continue the past patterns of spending on space activities even under extreme circumstances.

Future Space Funding: The actual distribution of federal funds for space activities (F-3) peaked at 1% of the GNP in 1966 and fell to 0.34% in 1980. The average rate of federal-government spending on space activities was 0.51% of the GNP between 1960 and 1980. The total was about $269 billion over 22 years in 1982 dollars.

F-3 **FEDERAL EXPENDITURES ON SPACE ACTIVITIES**
Civilian and military spending by the government on space activities since 1960. NASA spent most of the civilian funds and DOD spent most of the military funds.



Long trends in the U.S. economy and the federal budget suggest a number of ways to project future government spending on space activities, providing there are no drastic long-range changes in space policy. Some can be given as follows for a 22-yr period, the sums in billions of dollars:

Assumption	1982-2004 totals
Constant-dollar, point extrapolation	235
Constant-dollar, average extrapolation	269
1/3 DOD plus 2/3 NASA, average extrapolation	430
0.51% of GNP, average extrapolation	510
1% of GNP, point extrapolation	1,000

"The dangers of not making long-term commitments are two-fold: An unnecessarily miserly approach to our nation's space program can be a self-fulfilling prophecy, and without a long-range perspective we run the risk of spending the money unwisely by fits and starts."

The first line was arrived at by taking the total space budget of 1980—$10.7 billion in 1982 dollars—and multiplying that by 22 years to find $235 billion (one kind of "constant dollar" extrapolation). At the other extreme, multiplying the peak value of 1% times the cumulative GNP for the next 22 years ($100 trillion) yields $1000 billion (one kind of constant-fraction-of-GNP extrapolation). As estimates of future space budgets, $235 billion would appear to be too small and $1,000 billion too large, because both of these numbers are "point" extrapolations and are not extrapolations of decades-long averages.

Next, the constant 1982 dollar expenditures of $269 billion over the last 22 years can be taken as the amount that will be spent on space over the next 22 years. Or, using the constant fraction, 0.51% of the GNP over the past 22 years, we can multiply 0.0051 × $100 trillion to estimate that the U.S. will spend $510 billion on space activities during the next 22 years.

And finally, we can see that during the last 22 years a third of the U.S. space budget came under the heading of "national security" (through DOD), which experienced a constant-dollar budget for 27 years. The remaining two-thirds of the space budget came under the heading of "other" (through NASA), which experienced a constant fraction of GNP for 27 years. Therefore, based on these 27-yr averages applied to 22-yr spans, we can estimate that the future space budget will be made up of 1/3 × $269 billion (1/3 constant dollar) plus 2/3 × 0.0051 × $100,000 billion (2/3 constant fraction of GNP), or $430 billion over the next 22 years—all in 1982 dollars.

It would be difficult to choose which of these extrapolations is most likely to occur, although the last method, giving $430 billion, is the most faithful application of the guidelines. The figure $390 ±121 billion covers the range of most likely outcomes.

But the precision of these numbers is much greater than the range of uncertainty in the assumptions allows, and the numbers can be rounded without significantly affecting the accuracy of the estimate. This results in an estimate that the U.S. will spend $400 ±100 billion on space activities over the next 22 years. It must be understood that the uncertainty of $100 billion is not a statistical factor, but an attempt to bracket the range of the most likely occurrences.

The extreme no-growth case suggests that the U.S. economy would generate $90 trillion, instead of $100 trillion, if pessimistic assumptions come about. By that reckoning, the federal government would spend 1/3 × $269 billion plus 2/3 × 0.0051 × $90,000 billion = $396 billion on space during the next 22 years. The impact of those pessimistic and historically unrealistic assumptions is clearly in the "noise level" for our purposes.

During the past 22 years, the U.S. spent $70 billion on the Apollo program and over $10 billion on the Shuttle program (1982 constant dollars). This means that, of the $269 billion spent on space, about one-third can be attributed directly to large national commitments, one-third to military spending and one-third to other NASA missions, such as space sciences, technology development, and aeronautical engineering. If these trends continue, one-third of $400 ±100 billion will be "discretionary monies" for future national commitments.

This leads to the conclusion that over the next 22 years the U.S. can realistically make a national commitment to a major space program amounting to $130 ±30 billion. This would start out at about $4 billion per year and grow steadily to $8 billion per year in 2004 as the GNP doubles.

Concluding Remarks: Past experience often proves a better guide to future actions than projections based on "first principles."

We have observed that the average growth rate of the U.S. GNP has varied very little from 3.18% per year over nearly a century and that the growth rate consists of a statistical average of many uncorrelated phenomena. This suggests that the average growth rate will change slowly in a time of the order of 31 years. We deduce from this that economic trends which have lasted for three decades will change only slowly over the next three decades. Our results are obtained from a consistent application of these concepts.

An affordable space program was defined as one not so large as to keep the GNP per capita from in-

creasing. In that sense, all of the alternatives discussed here are affordable. In other words, the U.S. can afford a much larger space program than any mentioned herein.

Over the long term the U.S. economy looks robust. Barring unforeseen and unprecedented difficulties it will generate a GNP of about $100 trillion during the next 22 years, 0.4 ±0.1% of which is likely to be spent by the government on space. Past patterns of spending suggest that one-third of this $400 billion will be available for major national commitments to large focused space programs.

Even though this size of space budget was deduced by a conservative analysis, $130 billion over 22 years would fund a much larger project than today's politicians and administrators are willing to suggest publicly. The dangers of not making major long-term commitments are twofold: An unnecessarily miserly approach to our nation's space program can be a self fulfilling prophecy, and without a long-range perspective we run the risk of spending the money unwisely by fits and starts.

The U.S. can demonstrate leadership and sound stewardship of its resources by picking a long-range realistic goal in space and then developing the infrastructure necessary to achieve it. The goal should be chosen so that, as the program evolves, it derives economic, defense, political, and scientific benefits in dollars as well as in human satisfaction for the effort. Any goal fitting these criteria would be appropriate and provide continuity to our space program for decades ahead.

NEW VISIONS, FAILED DREAMS

The Lyndon B. Johnson Space Center is located in the middle of a 1620-acre marsh prairie at the edge of Clear Lake just off Galveston Bay, an area distinctive only for its peculiar lack of distinction. The space center itself looks much like a large, pleasant community college, only here the "students" are mostly middle-aged men who wear identification badges on their shirts, and speak in acronyms, saying things like "OSS," "the LDEF on STS-13," and "PFTA in conjunction with the RMS on STS-8."

But there is something disappointing about the neighborhood surrounding the space center. Here, at the edge of the nation's headquarters for the manned spaceflight program, just outside the entrance to the place where astronauts are trained and which the whole world knows as "Mission Control," there is a common assortment of fast-food restaurants, chain stores, realty offices, shoe hospitals, hotels, and muffler shops. Only the long banks of low white buildings facing the space center grounds—the offices of aerospace and electronics firms which do much of the technical work at the space center—give the neighborhood a high-tech character.

True, there is prosperity where there was only empty prairie, which is what the Clear Lake area was 25 years ago. But there has always been the expectation—at least in the early years—that the space center would bring new high-technology industry to Houston, and that the industry's spin-offs would make the Clear Lake area Houston's answer to the high-tech communities emerging around San Francisco and Boston, and in North Carolina and other states.

It didn't happen.

In the last year, however, that expectation has risen again. After some 25 years of confusion over just what we were doing in space anyway, a practical purpose for being there finally exists: money. Now, at last, there appears to be a commercial market for space technology, and investors and businesses across the nation are taking an interest. A number of recent developments have contributed to this new interest.

The space shuttle can now provide reliable and regular transportation into space for

ILLUSTRATION BY DENISE WATT

commercial satellites, as well as for pharmaceutical, glass, and metal processing experiments with large profit potential. A permanent, staffed space station, as proposed by President Reagan in January, will provide a base for the shuttle and for astronaut crews. Orbiting space platforms will soon carry factories that will make the drugs and other materials now in the experimental stage. And the federal government has been encouraging private sector involvement, with tax shelters and cooperative agreements as incentives, thus opening up new fields for satellite development, satellite launching services, and other private space-tech enterprises.

What are Houston's chances for cashing in on this new industry? The space center is about the only thing the city has going—other than the Medical Center—which is not in some way connected to the oil and gas industry. Last year the Houston area lost almost 96,000 jobs largely because of the end of the decade-long oil boom. By comparison, between 1977 and 1981 the city gained just over 10,000 a year.

So Houston has a special interest in the Johnson Space Center, with its odd-shaped windowless buildings and towers sticking up here and there. What exactly is this place? What do people do there? And what are we supposed to do with it after all these years of viewing it mainly as a "celebrity acquisition," as one NASA official describes it, a great boost for Houston's image, and an interesting tourist attraction?

Is JSC supposed to be a growing industry which will provide thousands of new jobs? A research center that will develop new technology that will create new jobs? A talent pool of highly trained and educated engineers who will leave government service and start space-tech businesses?

"One thing we have to keep in perspective," says Lee Tucker, executive assistant to Houston Chamber of Commerce president Louie Welch, "when Columbus discovered America, he didn't come right over and start New York."

IN THE BEGINNING, we did expect something big to start here. The new manned spacecraft center was to make Houston a world-class city. Houston was now going to be something besides a cowtown with oil in the back pasture. It was going to be the portal to the future, to space, the new frontier. After Rep. Albert Thomas of Houston called up the Chamber of Commerce in September 1961 to announce that Houston had been selected as the site for the new space lab, the chamber gushed that "the new space laboratory will make Houston the headquarters of the most advanced technology in the world."

Houston had fought hard for the space lab, competing with seemingly better sites all over the country. The race to the moon was going to inject billions of federal dollars into the country's economy, and everybody wanted some of it. President John F. Kennedy was particularly keen to have the lab located in Boston, which already had plenty of engineers and scientists to work in it. Virginia politicians wanted the lab at the Langley Research Center, where the Space Task Group, about 75 engineers working for Project Mercury, was already in place. Others wanted the site in Louisiana, California, Florida.

Houston didn't have any scientists or engineers, or any supporting industry, but the warm climate was a plus, since the new lab would have to be constructed in a hurry. And access to the coast was thought to be important, though it turned out it was not.

What Houston really had that the fledgling National Aeronautics and Space Administration needed for President Kennedy's ambitious space program were the politicians. It also had some timely cooperation between a university and an oil company.

The most prominent politician, of course, was Lyndon Johnson, after whom the space center was renamed in 1973.

LBJ was "anxious" to have Houston be the site of the new space center, recalls former NASA administrator James E. Webb, now retired in Washington, D.C. And for LBJ's efforts on behalf of Houston, and on behalf of the space program altogether, he is amply memorialized in the JSC visitor center with an entire room filled with memorabilia—photographs, books, desk, chairs, flags, and significant documents.

At the time of site selection Johnson was vice president of the United States and also chairman of President Kennedy's National Aeronautics and Space Council. Before that, as Senate majority leader, he was chairman of the Senate Space Committee as well as chairman of the Preparedness Investigating Subcommittee of the Senate Armed Services Committee.

Johnson was important to the space center, but there were others, too. Down the hall from the Johnson exhibit at the visitor center hangs a color photograph of Congressman Olin E. Teague. "Tiger" Teague, after whom the visitor center is named, was a war hero and part of his district included the bay area. Teague was, by coincidence, chairman of the House Space Committee at the time the site for the new manned spacecraft center was selected in 1961.

The key politician, however, was Rep. Albert Thomas of Houston, then in his twenty-fourth year in Congress. Thomas, a shrewd and gentlemanly politician who wore bow ties and taught JFK the rudiments of Congress, was chairman of the House Appropriations subcommittee which passed on NASA's budget, as well as chairman of the subcommittee which appropriated any additional money needed by the space agency.

NASA needed Thomas' support. But it also needed 1000 acres of land with a university nearby, and Thomas helped with that, too. The university was supposed to

(continued on page 124)

SPACE CENTER

(continued from page 107)

provide research talent and educational opportunities for the young engineers who would be hired by the new space lab. Certainly any university located near the new center would benefit from the research dollars that would be flowing out of the laboratory.

The land upon which the space center now sits was then part of a 32,000-acre parcel belonging to the Humble Oil and Refining Company (now Exxon), which had decided that the property was too valuable for just grazing cattle, recalls John B. Turner, president of the Friendswood Development Company.

In the winter of 1961, about six months before the site for the new manned spacecraft center was announced, a meeting was held at Albert Thomas' office in Washington, D.C. According to the recollection of a retired newspaper publisher who was there, Jim Webb, the newly appointed administrator of NASA, said "Albert, we ought to get that space center in the southwest."

There followed a brief discussion of universities in the southwest. "How about Rice [Institute] in Houston?" said Thomas, a Rice graduate.

Though Rice Institute (now Rice University) was—and still is—basically a small undergraduate facility, Webb said he thought Rice might work, so Thomas called his old friend and classmate George Brown, longtime chairman of the Rice board of trustees and a founder of the engineering firm of Brown & Root, at Brown's Washington hotel suite. Webb, Thomas, and the newspaperman joined Brown for dinner, and on that evening, "So help me," says the newspaperman, "that damn thing—the site—was born."

"The skids were greased. Albert Thomas just picked that space center up and laid it in our laps."

In the months that followed, Rice beefed up its faculty a bit and added a Space Sciences Department, now the Department of Space Physics and Astronomy. It was said to be the first department of its kind in the nation, though NASA also helped to establish similar programs at other universities.

And, as a result of some swift but intense negotiations between George Brown and Morgan Davis, then chairman of the board at Humble, the oil company which donated 1000 acres to Rice, which in turn donated it to NASA. There would have been no tax benefit for Humble in donating the property directly to the government. NASA decided shortly after the agreement was signed ("The ink was hardly dry," recalls Malcolm Lovett, then counsel to the university) that 1000 acres wasn't enough. An additional 600 acres was needed, which Humble swapped to Rice for 100 acres of land near the Southwest Freeway. Rice then sold the 600 acres in Clear Lake to the government for about $2 million, according to Lovett, who in addition to being university counsel was then a member of the board of trustees. NASA also gave the university a grant of about $1.8 million to build a Space Sciences Building.

Houston needs a stronger university base to realize its technological dreams. "Dallas, Austin, Bryan, have stronger university bases than Houston," Stauffer says.

It was a happy deal for Rice, which got a new building and a new department. The Space Physics and Astronomy program now has 31 graduate students and 13 faculty members, and receives about $1.4 million a year from various sources—including the Department of Defense, the National Science Foundation, and the Welch Foundation—for space-related research. About

38-036 O - 84 - 26

$600,000 of that money comes from NASA in Washington, D.C., for work in areas such as satellite data analysis and the theory of the earth's magnetic fields. Rice does very little work for the Johnson Space Center, mainly because the space center itself does little theoretical or scientific research.

The NASA arrangement was also a happy deal for Humble, which formed Friendswood Development Company and had been developing part of the remaining 30,000 acres into Clear Lake City. The University of Houston also benefited, later receiving a donation of land from Friendswood to build a campus in the Clear Lake development.

Brown & Root won the $1.5 million contract to design the new $60 million space lab. Albert Thomas got a post office in Clear Lake named after him. And Houston got the astronauts, the engineers, and a whole new image as the center of the most advanced technology in the world. It was fun and exciting. And it was going to be the biggest thing to happen to Houston since the opening of the Ship Channel in 1915. But it didn't quite turn out that way.

THE SPACE SHUTTLE does not take off or land at the Johnson Space Center, as is often thought. Nor are space rockets designed or built there. The space center is, rather, a headquarters, a coordinating facility for that part of the national space program which involves astronauts.

As an industry it has never been a major employer. There are about 9000 people working there, compared to 38,000 at the Texas Medical Center, for instance. Peak employment occurred in the late 1960s, just before the first astronauts stepped onto the moon and promptly lost the interest of the public and the support of the politicians, sending the space program into a tailspin from which it is just now recovering.

There are now about half as many people working at JSC today as there were at the peak of the space program, and few of them have the advanced degrees that are the foundation of a research center. Out of 3399 government employees at the space center, about two-thirds are scientists and engineers, and most of them only have undergraduate degrees. Only 524 federal employees at the space center have Masters degrees, and 143 PhD or LLD degrees.

The Johnson Space Center is not a research facility, although it does have a small aeronautics research program which last year spent about $15 million developing new systems for the shuttle and studying ways to design and use the space station. Much of that work was contracted to private industry outside the state.

Though some of NASA's nine other major facilities are research-oriented, particularly in satellite and rocket technology, JSC has always had a management role, as the manned spaceflight program itself has always been more of a management problem than a technological problem: how to manage hundreds of thousands of people working on hundreds of different tasks at numerous different firms all over the country, make it all come together on time and work. The triumph of JSC is really a triumph of management technique.

Overall, the main task of JSC, which receives 30 percent of the total NASA budget of some $7 billion, has been to coordinate research and development taking place in other parts of the country, primarily in those areas which had the technology and industry twenty years ago, and still have it.

Last year, for instance, NASA paid Texas firms or firms with employees in Texas $454 million, of which approximately half went to astronaut training, research, maintenance, and work in mission control, and other technological programs in support of the space shuttles Columbia and Challenger. By comparison, firms in the state of California, where the aerospace industry is headquartered, received $2.3 billion, of which about half went to Rockwell International in Downey for designing, developing, and testing the space shuttle orbiter. Florida businesses received $651 million.

Overall, of money spent by the space center itself (not by NASA as a whole) in fiscal year 1982, Texas received about 20 percent of the total business contracts.

Of the $18.7 million paid to educational and non-profit research institutions, almost 40 percent went to Massachusetts, 33 percent of it to the Charles Stark Draper Laboratories in Cambridge.

California received the next largest amount, almost thirteen percent of the total, with five percent of that going to the California Insitute.

Texas institutions ranked third with twelve percent of the total. Half of that went to Texas A&M and most of the rest was spread out between Baylor and the University of Texas medical schools in Houston and Galveston, as well as UT branches in Dallas, Austin, and San Antonio.

The University of Houston at Clear Lake City received only .53 percent--$92,600.

SO THE JOHNSON Space Center is probably not going to serve Houston as a high-tech research center. What about the space industry itself? How much of that might Houston get?

Clearly, Houston has come a long way since the NASA layoffs in the early 1970s, when the moon mission had been completed and JSC engineers were supporting themselves making purses and selling fishing tackle.

"Nobody left the space program voluntarily in the early days," says J.L. Taylor, director of the Houston Chamber of Commerce's Economic Development Division. "The difficulty was nobody could figure out what to do [outside the program].

"When NASA started laying people off in the early Seventies, a lot of these people couldn't find jobs. And part of the problem was that what they were involved in was so esoteric, so far out, that private industry couldn't relate to what they had to offer."

That picture has changed somewhat, but JSC engineers still complain that business people don't understand what they are talking about. "Quite often I am accused of not being in touch with reality, of being a space cadet," says one engineer.

Still, there are new job opportunities for engineers who want to leave the space program. Few do. Working for NASA still has charisma. But, "there is money to be made in working for aerospace companies on payload integration--making sure the satellite won't come loose on the space shuttle, for instance," says one NASA engineer, who adds that recently, for the first time ever, private firms have been offering him jobs.

Other than payload integration, which is working with satellite and materials processing firms which want to use the shuttle ("payload" refers to the revenue-producing or useful cargo of the shuttle), there are three basic areas of opportunity for growth in the private space industry. They are in remote-sensing and communications satellites, satellite launching services, and materials processing-- manufacturing drugs, metals, and fiber optics in the low gravity of space.

What are Houston's chances in any of these areas?

The Johnson Space Center's expertise is not satellites or rockets. The satellite and telecommunications industry is already well established in California, which in addition to having a state space agency, also has the Jet Propulsion Laboratory and most of the aerospace and electronics industry. "California is very active," says Greg Fawkes of the Space Enterprise Project, a research foundation affiliated with the U.S. Chamber of Commerce promoting commercialization of space.

There is some hope that pharmaceutical companies and other materials processing industries might want to locate here in order to be close to the space center as it receives information from the astronaut crews conducting experiments on shuttle flights. At least one pharmaceutical company reportedly has plans to move to the Clear Lake area. However, it is not yet clear why it should be necessary for such firms to locate here, since the same information could be available almost anywhere.

There is, though, considerable excitement and attention focused on some of the now-retired stars of the Johnson Space

Center and what they might produce in some of the areas of satellite and launch services and industrial space vehicles.

"I think that the expectations for the return to the city of Houston were too high," says the Chamber of Commerce's Jay Taylor. "Not too high, but expecting returns overnight. In any high-tech development there is an average of ten to fifteen years before it gets to commercialization.

"We've had too much of a focus on the physical facilities. The location. That misses the point. The real asset to Houston was the people," says Taylor. "Most of the people in the program were very young engineers. Now they've matured, put down roots. They've become Houstonians.

"Twenty years from now, people like Deke Slayton and Max Faget will be chairmen of the boards of major corporations."

Deke Slayton and Max Faget are two of the luminaries of the space program, part of a small constellation of retired JSC managers now pioneering private space-tech businesses in Houston. These companies are in the early development stage, and there is a great deal of excitement about them, although, as Taylor points out, it will be a decade or more before we can expect many jobs to result.

Slayton, one of the original seven astronauts chosen for the Mercury program and later assistant program manager for the space shuttle, is now president of Space Services, Inc., of America, a company formed by Houston developer David Hannah, Jr. in October 1980. Space Services, Inc., which in 1982 wowed a great many people with the first launching of a privately financed rocket, the Conestoga 1, over the Gulf of Mexico, is in the satellite-launching business and plans ultimately to launch its own remote-sensing satellites. Slayton and Hannah don't have any customers yet, but in the meantime their company is working on its satellites and payloads.

Faget, a 35-year veteran of NASA and its predecessor, the National Advisory Committee for Aeronautics, is former director of engineering and development at JSC and the innovator of the Mercury spacecraft, director of the design team for the Apollo program, and preliminary designer of the space shuttle. Faget is now head of his own company, Space Industries, Inc., which he describes as "a very, very high-risk thing" which he has to sell to "a few people willing to invest in it... people looking for high-tech things to do."

Faget is hoping to put an industrial space platform into orbit which would be visited from time to time by the space shuttle. The facility would manufacture pharmaceuticals, fiber optics, and other processed materials in the micro-gravity of outer space. Johnson and Johnson plans to have a similar manufacturing facility in orbit by 1986. Faget's platform is just out of the design stage and he is still looking for funds.

There are other lesser luminaries now retired from the space program and active in Houston. Owen Morris, for instance, the manager of the Apollo program, has started a small firm, Eagle Engineering, with a full-time staff of about twenty, on El Camino Real in Clear Lake City. Max Faget is one of five vice-presidents and is in new systems development. Eagle Engineering provides management and technical services to mainly aerospace companies.

Dick Johnston, former director of Life Sciences at the space center, is now vice president for program development at the Texas Medical Center and works with the Houston Area Research Center in The Woodlands. Johnston is working hard to prod Houston into capitalizing on the medical technology and research which has come out of the space center, largely as a result of its role in monitoring the responses of astronauts to outer space. This is probably one of the only areas in which Houston has a unique advantage in the space-tech field. But how to translate this new technology into investment and business opportunities and products that are made here remains a problem for the city.

President Reagan's stated goal to promote commercialization of space and build a space station within the next ten years has given an additional boost to the city's hopes for a new high-tech industry to create new jobs. Those hopes intensified with NASA's February announcement that the Johnson Space Center would be the headquarters for the development of the space station, which is not to be as large a program as the space shuttle. Officials at JSC do not expect to do any hiring, and research and development funds will likely flow to other states as they have in the past. At the very least, however, the space station means greater stability and continuity for the space center.

As for space business, "Houston is very active," says Fawkes; pointing as an example to the Space Foundation, a Houston organization devoted to funding space-tech research and to promoting information exchange between investors and space specialists. But other areas are active, too. "Nationally a number of firms are springing up which want to develop new products and services and new transportation.

"At this point in time the advantage is going to go to the area that puts it all together—talent, money, good ideas."

"A deliberate effort of creating a thing is what it takes to develop high-tech research and industry of any kind," says Tom Stauffer, chancellor of the University of Houston at Clear Lake and chairman of the Houston Chamber of Commerce's Economic Diversification Planning Committee. Stauffer believes that the major benefit of NASA here is as a magnet to other engineers. NASA, he says, was not created for jumping full-blown into new industries.

Houston needs a stronger university base, too, if it wants to realize its technological dreams. "Dallas, Austin, Bryan, have stronger university bases than Houston," Stauffer says. "Rice needs to look beyond its own walls."

The city needs to develop venture capital expertise outside of the energy field, adds Stauffer. It needs to solve its transportation problems; develop cooperation among local industry, universities, and government and set up a committee, a plan, a goal, as other states and cities have been doing for years. George Mitchell has been doing this with the Houston Area Research Center in The Woodlands, north of the city.

THE OFFICES OF Gerald Griffin, director of the Johnson Space Center, are on the ninth floor of Building 1. From the windows of his office you can see most of the space center campus: mission control; the moon rock laboratory; the space food and space suit labs; the green towers of the noise and vibration testing facility; the building where the astronauts, now 75 of them, have their offices and classrooms.

Griffin is a Texan and a graduate of Texas A&M. A former flight director at the space center, he is trim and compact, not very tall, with smiling blue eyes. President Reagan had not yet announced that he would propose to Congress an $8 billion program to build the space station, but Griffin was obviously in a happy mood.

The Johnson Space Center is "not the panacea" for Houston's problems, says Griffin. "It's just a piece of the puzzle. But I think the business that is generated around space activities could be a major factor in the puzzle for the Houston area."

The space center will provide "a focus" and "a reason" for high-tech companies to develop here, "a rallying point for this area."

And there is still the image benefit. "The people of Houston don't look upon anything as impossible," says Griffin, beaming. "The moon mission and the whole space endeavor fit that, and I think people tend to migrate here because that spirit's here."

There are grand opportunities in space which most likely will benefit other parts of the country more, just as they always have. Houston has some space-tech resources to draw on, if it can figure out how. Certainly there is a willingness and excitement about doing that. But it does not appear that space business is going to become a major industry for the city.

"We need to concentrate on our strengths," says Texas Commerce Bank economist Carol Bennett. "Houston needs to figure out what its assets and liabilities are and work with them." ●

WANTED: A SPACE POLICY TO DEFEND AMERICA

INTRODUCTION

In his address of March 23, 1983, President Reagan directed a "comprehensive and intensive effort to define a long-term research and development program, to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles." The media quickly, but inappropriately, characterized it as the "Star Wars" initiative.

The message was clearly directed at goals rather than means. The technological basis for this fundamental policy shift involves new technology and innovative concepts in space. Prevailing military space policy does not explicitly provide the clear directives needed to support the President's initiative. It is now essential, therefore, to reexamine and revise U.S. military space policy.

BACKGROUND--SPACE IN NATIONAL POLICY

Present military space policy is set within the framework of national space policy, which was first established by the National Aeronautics and Space Act of 1958. While the NAS Act encompasses the civilian and military aspects of space, the specifics of the act deal mostly with the establishment of the civil space program and the organization of the National Aeronautics and Space Administration (NASA). It was intended to project the peaceful and scientific objectives of the space program to the world community.

The NAS Act set forth the basic national policy for a vigorous U.S. response to the Soviet space challenge. It established executive authority for a new class of programs that did not fit existing civilian agency structures. Congress

Note: Nothing written here is to be construed as necessarily reflecting the views of The Heritage Foundation or as an attempt to aid or hinder the passage of any bill before Congress.

recognized that the technical skills and resources needed to achieve meaningful results would necessarily draw on the same industrial skills that supported military development programs.

The NAS Act is explicit in assigning the responsibility for "activities peculiar to or primarily associated with the development of weapons systems, military operations, or the defense of the United States..." to the Department of Defense. It contains no language that excludes or prohibits military use of space for national defense. The governing principle is that military space policy derives from national defense policy, consistent with U.S. laws and treaty obligations.

The basis for a military space policy consistent with international law is derived from the right of all nations to self-defense, a long recognized principle. Within this framework, military activities in space are constrained by specific treaties, principally the 1967 U.N. Outer Space Treaty and the 1972 Anti-Ballistic Missile (ABM) Treaty.

The Outer Space Treaty contains explicit prohibitions against stationing in outer space any object carrying a nuclear weapon or any other weapon of mass destruction, although there are no provisions for verifying treaty compliance. It further prohibits establishing military bases and testing weapons on celestial bodies. Neither of these prohibitions is an impediment to the development of U.S. military space policy, space operations, and new kinds of space weapons currently being considered for deployment. For example, space-based high energy lasers or particle beam weapons are not considered "weapons of mass destruction" and so are not covered by the Outer Space Treaty.

Unlike the U.N. Outer Space Treaty (an agreement signed by more than eighty countries), the ABM Treaty is a bilateral agreement signed in May 1972, by the United States and the Soviet Union as part of SALT I. This treaty restricts the development and deployment of ballistic missile defense systems, specifically including space-based systems. The Treaty does permit research and development on ballistic missile defense technology. Furthermore, the United States went on record that failure to achieve more comprehensive strategic offense arms limitations within five years (of the date of signing), could constitute a basis for withdrawal from the ABM Treaty.

There are several reasons for questioning whether the United States should continue to be bound by the ABM Treaty.[1] However, in any event the Treaty does not preclude a military space policy that includes the conceptual development, and supporting research and technology for space-based ballistic missile defense systems.

3

PRESENT U.S. MILITARY SPACE POLICY

Present U.S. military space policy derives from the national space policy announced by President Reagan on July 4, 1982.[2] It closely parallels the policy developed under the Carter Administration, and reaffirms the national security basis for a military space program. The United States has consistently endorsed the use of space for national defense.

The most recent review of military space policy recognizes that space activities support such important military functions as command and control, communications, navigation, environmental monitoring, warning, surveillance, and space defense. The policy directs that future U.S. space programs move toward operational capability. This orientation places importance on the ability of space systems to survive and endure under wartime conditions. In addition, the policy explicitly directs the continued development of an anti-satellite (ASAT) capability with two objectives. The first is to deter attacks on U.S. satellites. The second is to have the ability to attack the space assets of an adversary in time of war.

President Carter endorsed the development of an ASAT weapon in Presidential Directive-37, which spelled out U.S. military space policy. The ASAT weapon development was undertaken in 1978 in response to continued Soviet development and testing of such a weapon.

This program represented a distinct departure from previous military space developments; for the first time since the 1960s, the U.S. undertook a space weapon development program. This program was announced concurrently with the initiation of talks with the Soviet Union on limiting the deployment of ASAT weapons in space. U.S. military space policy reluctantly embraced the development of a single space weapon aimed primarily at matching a Soviet capability. The development of weapons for ballistic missile defense, however, would not have been encouraged by the Carter policy.

As the executive agent for military space activities, the Air Force is the principal architect of U.S. military space posture. Air Force doctrine describing military space operation is stated in Air Force Manual 1-1. This delineates three types of space operations: space support, force enhancement, and defense of space assets.

---

[2] Present U.S. space policy is the result of an interagency review requested by the President in August 1981. While some of its details remain classified, the essential thrust of the policy is contained in a White House Fact Sheet on National Space Policy, dated July 4, 1982. The military aspects of the policy are outlined further in a Department of Defense Fact Sheet on DoD Space Policy, dated August 11, 1982.

Space support operations involve the construction and operation of facilities shared by a number of military users. The most visible of these are the launch complexes that put military spacecraft into space. In addition, facilities like the Satellite Control Facility provide support to military satellites in orbit. Other radar and optical tracking stations feed satellite data to the Space Computation Center inside Cheyenne Mountain, near Colorado Springs. These facilities provide surveillance over all space activities, including the orbiting of non-U.S. satellites.

Force enhancement describes the military satellite programs that support ("enhance") other traditional military functions. These programs do not directly involve weapons; they provide information and communications for the more effective command and control of military operations.

Reconnaissance satellites provide critical data on Soviet force levels and disposition, facilities, and weapon characteristics. They are the key element in verification of arms limitation agreements, the "national technical means" cited in the SALT agreement. The satellites of the Defense Support Program maintain a continuous surveillance over Soviet missile launch areas, to warn of attack and signal the launch of Soviet spacecraft. Satellite-borne detectors also signal nuclear detonations. A system of military satellites provides worldwide weather observation. These and other observation satellites provide a capability to monitor events on a worldwide basis that would not be practical by any other means.

Military satellites provide effective communications to U.S. forces around the world. Continuous quality communications service is provided to key U.S. installations overseas. These systems extend reliable communications to sometimes remote foreign areas. They also insure that the communication links are under U.S. control. In crisis or rapid deployment situations, communications at new locations can be quickly established. The Defense Satellite Communications System provides heavy route backbone communications on a worldwide basis.

The Fleet Satellite Communications System provides reliable communications to Navy tactical units at sea. The Air Force Satellite Communications system provides a more survivable means of commanding a retaliatory strike in the event of nuclear war. The Global Positioning System will provide military units the ability to accurately determine their position on a worldwide basis at any time. The new Milstar system will greatly increase the survivability of key military communications links and enhance their ability to work effectively in the presence of jamming. Military satellite communications are important to enhancing the ability of U.S. forces to operate effectively anywhere in the world.

Space defense (defense of space assets) is the third category of space operations. It is a set of missions established in 1978, with the space policy delineated in PD-37. The space defense mission includes the development of the U.S. anti-satellite system, the surveillance and tracking of all objects in space, measures to protect U.S. satellites and increase the survivability of space systems, and the command and control of the space defense mission.

By establishing these programs, the United States took action in response to the evident Soviet capability for attacking U.S. military satellites. At that time the U.S. lacked the capability to directly respond to a Soviet attack on its space assets. In the event of such an attack, it could either respond by other military means, risking a broadening military confrontation, or do nothing. U.S. military options for responding to Soviet attacks on U.S. space assets remain the same today. The program to field a U.S. ASAT weapon has yet to reach the final stages of testing. In the meantime, the risks associated with undefended space assets have increased with the growing use of space systems in U.S. military operations.

SPACE DOCTRINE AND MAD

Air Force space doctrine has been structured to support current U.S. defense policy. Strategic deterrence policy has long been built on the capability to deliver a devastating retaliatory blow in response to a Soviet nuclear attack. The policy of Mutual Assured Destruction (MAD) has placed the greatest priority on building and maintaining the readiness of the forces necessary to deliver the offensive counterstrike.

The missions spelled out in Air Force space doctrine are designed to support the offensive weapons systems that are the backbone of U.S. strategic defense policy. The Air Force reconnaissance mission keeps tabs on Soviet missile launchers and provides accurate targeting information. The surveillance mission provides warning of the launching of a missile attack, and information on the expected targets. Satellite communications provide essential links to collect surveillance data for processing and assessment, and for dissemination of Emergency Action Messages to the retaliatory nuclear strike forces. The missions spelled out in Air Force space doctrine are designed to support the offensive weapons systems that are the backbone of U.S. strategic defense policy.

Even the U.S. ASAT program is aimed at deterrence by retaliation. It provides only very limited defense of U.S. satellites in space. It is intended primarily to assure the Soviets that an attack on U.S. space assets could be met in kind with a counter-attack.

Air Force space doctrine also supports the policy of MAD by what it does not provide--a role for ballistic missile defense. Even the task of conducting anti-ballistic missile research, which is permitted under the terms of the ABM Treaty, has been assigned to the Army, and this effort has been centered on defense of hardened strategic assets against Soviet warheads in the final stages of their flight.

In not providing a ballistic missile defense mission, Air Force space doctrine has adhered to U.S. strategic policy of MAD, and the delineation of service roles and missions by the Department of Defense.

The concept of deterrence through Mutual Assured Destruction requires that the U.S. and the U.S.S.R. have the capability to destroy each other as viable societies. This concept (expounded by Robert McNamara in 1962), became the basis for U.S. strategic policy. It was this policy which guided the U.S. position in the Strategic Arms Limitation Talks.

The MAD concept requires that neither side have an effective ballistic missile defense system. Such a system would disrupt the balance of nuclear force levels that the SALT I Treaty sought to establish. Hence, the negotiation of the ABM Treaty became linked to the negotiation of ceilings on offensive nuclear forces. Given rough equivalence of force levels and no effective ballistic missile defense, the MAD concept holds that the cities and populations of each country are held hostage to the other side.

Within the numerical force levels permitted under the SALT agreement, the Soviets developed and deployed a new generation of ICBMs with greatly increased accuracy. These missiles have made large segments of the U.S. nuclear deterrent vulnerable to a Soviet first strike. There is no evidence that the Soviet Union ever subscribed to the concept of MAD. On the contrary, their writings on strategic doctrine have emphasized the merits of a massive use of nuclear weapons against U.S. nuclear retaliation forces, and the advantage of a surprise preemptive strike.

Along with their build-up of strategic nuclear forces, the Soviets have continued to strengthen their defensive systems. While the United States all but abandoned development of ballistic missile defense systems, the Soviets upgraded ABM defenses. These measures have exploited loopholes and, in some instances, violated the ABM Treaty.[3] At the same time, the Soviets have continued to devote substantial resources to civil defense.[4] The clear evidence indicates that the Soviets have

[4] According to the Central Intelligence Agency, the U.S.S.R. is spending about $2.5 billion a year on civil defense. The U.S. spent $147 million for civil defense in FY 1983.

been striving for nuclear superiority. The MAD concept has not worked.

The MAD framework for U.S. strategic policy was established in the early 1960s. The technological basis for this policy is more than twenty years old. Since that time, technology has advanced markedly in a number of areas. Space missions that were then only concepts near the limits of further expectation now are routine. The U.S. posseses the know-how to build space systems that can be moved and pointed with extreme accuracy, and to acquire and track objects in space. The U.S. has developed small data processors that are the equivalent of what was then a room full of computers. And the U.S. can build weapons effective over the vast distances of space.

Over the years, the application of these advances in technology has been encouraged in those areas that support underlying strategic policy. Advances that tend to undermine the technological foundation of this policy have, at best, not been fully exploited. Under the MAD policy, the United States supported vigorous development and deployment of offensive weapon capability. After the initiation of the SALT process, only minimal support was given to ballistic missile defense technology. The potential of new technological approaches to ballistic missile defense in space has been further thwarted by the lack of a meaningful Air Force mission in ballistic missile defense. Such a mission makes little sense as long as the U.S. continues to cling to a strategic policy based solely on MAD.

NEED FOR A REVISED SPACE POLICY

There is nothing in the National Aeronautics and Space Act that prohibits the development and deployment of weapons in space. If there is a failure to exploit the full capabilities of space for national defense, it is traceable to the policies the United States has chosen.

Intercontinental ballistic missiles (ICBMs), once launched, have been seen as invincible weapons. Rather than attempt to devise a direct defense against ICBM attack, the United States has chosen to insure a devastating retaliatory attack as a deterrent. It has devoted resources and technology to achieving diversity and dispersal of nuclear forces to assure that the retaliatory blow can be delivered. Now the high accuracy of the newer Soviet ICBMs and increasing numbers of submarine launched ballistic missiles (SLBMs) have cast grave doubt on the survivability of two of the three components of U.S. strategic forces. The perceived strategic stability achieved under the MAD doctrine already has been shattered.

At the same time, the United States has failed to pursue vigorously the search for alternatives that might some day offer the promise of an effective defense against ballistic missile

attack. The essence of the Defense Technologies Study initiated by President Reagan is a plan that will direct the best technical resources toward a more acceptable solution to the strategic defense problem. It involves new concepts for systems in space.

It has long been recognized that the most vulnerable portion of the flight of an ICBM is the boost into orbit, when the large rockets are already stressed by thrust and vibration. Any defensive attack on ICBMs during this phase necessarily involves overflight of the Soviet land mass and that can only be accomplished by defensive space-based weapons. The mid-course portion of a missile flight takes place in space.

Any attempt to destroy a missile during this phase implies an attack in space. This holds whether the defensive weapon is based on the ground or in space. The boost and mid-course phases consume most of the total flight time of an ICBM, where the destructive weapon is the most distant from its target.

The Department of Defense has spent over $1 billion on direct energy weapons. By far the largest amount has been spent on the development of high energy lasers. Most of the money has been spent on developing the basic technology needed to build practical weapons and on research on the physical mechanisms involved. The technology includes building lasers capable of megawatt power levels, large optical systems to form beams, and pointing and tracking systems of extraordinary accuracy to direct a beam and hold it on target. It includes experiments to determine the effects of the atmosphere on the beam and the damage effects on optical surfaces and target materials.

High energy lasers can be built and made into effective weapons. More development work is needed to assess the cost and effectiveness of particular applications of these new weapons in comparison with more conventional weapons. These comparisons can only be made when the laser weapon is designed to perform a particular military mission.

The military applications are structured from the missions of the services. The Army is investigating the effectiveness of laser weapons for short range battlefield use and air defense. The Navy's interest has focused on fleet defense against aircraft and missiles. Much of the Air Force effort has been centered on the operation of an airborne high energy laser suited to Air Force missions. The substantial Defense Advanced Research Projects Agency (DARPA) Triad program, although suited for space application, has been on non-mission oriented technology development.

The application of this technology to space missions is lagging, in part because of an insufficient statement of mission requirements. The mission requirements are lacking because of a defense policy focused heavily on strategic offensive capability.

The technology "push" for ballistic missile defense in space is evident. The mission requirements "pull" for the application of that technology has been absent.

The most vocal support for moving ahead on military applications of space-based high energy lasers has come not from the Air Force but from Congress and the General Accounting Office. Senator Malcolm Wallop (R.-Wyo.), a strong supporter of space-based lasers, pointed out that "Since 1981 the Senate has voted twice, by 91 to 3 and unanimously, to tell the Department of Defense to build a space-based laser weapon as quickly as possible.... But...neither the necessary funds nor the essential direction have been brought to this area."

The strongest and most detailed case for a new national strategy incorporating a strong ballistic missile defense program has come from High Frontier, a non-profit organization, headed by Lt. Gen. Daniel O. Graham, USA (Ret.). It has not come from the Department of Defense or closely allied sources.

The orientation of U.S. military space policy and the Air Force Space Doctrine that derives from that policy are significant contributors to the lack of requirements pull. Lack of organizational focus has contributed as well. Prior to the activation of the Air Force Space Command in September 1982, there was no single organization within the Department of Defense with responsibility for the development and operation of space systems. This responsibility was spread over at least four major Air Force commands, with other Air Force, Navy, Army, and Defense agencies participating in particular aspects of space.

The establishment of the new Space Command should be only an interim step toward the formation of a separate military service, with responsibility for space as a military realm, on an equal footing with land, sea, and air. The critical deficiency has been a lack of advocacy for space missions outside of the framework of established Air Force doctrine.

The Air Force has recently moved to amend its space doctrine to accommodate a broader range of space missions. Under the more recent doctrine,[5] a new mission category has been added, called "potential warfighting missions." In this doctrine, the name of the mission of space defense appears to have been replaced by "space control and superiority." In addition, a broad range of potential missions for space-based weapon systems has been added. Included is the statement that, "Such systems could be able to provide target damage against widely distributed and increasing numbers of enemy counterforce and countervalue surface targets." Unfortunately, the language does not make it clear whether this language is intended as a broadening of Air Force space doctrine

---

5 Military Space Doctrine, Air Force Manual 1-6, 15 October 1982.

to support new strategic ballistic missile defense initiatives. The potential shift in doctrine must be clearly and unambiguously reflected in stated U.S. military space policy. The new Air Force doctrine must have the necessary foundation at the national policy level.

CONCLUSION

Space policy alone is not the issue. The present space policy is designed to support an obsolete strategic policy. In this context, President Reagan's address of March 23 laid the political foundation for a return to the traditional concept that the military should defend the country against attack.

If advanced technology in space holds the promise of an effective defense against nuclear attack, then the achievement of that goal is inhibited by a number of barriers. Some of the barriers are technological and cannot be overcome without determined effort. Other barriers lie in policies of the U.S.' own choice. These can and must be changed. One positive step would be support for a new space policy that seeks legitimate opportunities in space to achieve an effective ballistic missile defense.

CHAPTER FOURTEEN

SPACE PROGRAM BENEFITS

I. STUDIES OF THE ECONOMIC EFFECTS OF NASA R. & D.

By David Bruce Hack
Analyst in Science and Technology

A. Introduction

Some would say that all manner of U.S. national problems—ranging from energy supply, to inflation, to loss of confidence in the dollar abroad, to urban youth unemployment and environmental protection—may perhaps be solved by liberal applications of space research plus technology transfer. The opposite extreme view is that space research and technology development is a waste of money that could be spent more directly on the solution of problems which press directly. NASA has addressed this polarization of view by seeking a more scientific basis for estimating the non-mission net social benefit of NASA programs. The purpose here is to review the principal reports resulting from this NASA-sponsored effort—together with a General Accounting Office (GAO) assessment of one of those reports—and to comment on a scattered few studies by aerospace industry authors.

The literature review here on economic effects of NASA's R&D can be divided into three categories: (1) short-run effects on the national economy arising from increased demands for goods and services; (2) long-run effects arising from increased supply of goods and services; and (3) case studies and sectoral/regional economic effects studies intended to support by illustration the effects of types (1) and (2).

B. Short-Run Demand Effects—The Chase Study

It is commonplace to read discussions in the print mass media of the effects of Government spending on aggregate demand and gross national product (GNP). This is testimony to the wide acceptance and public application of the economic ideas derived from John Maynard Keynes over the last 40 years. Such effects of Government spending are in fact so widely discussed that they may be the only effects thought of by some whose acquaintance with economic thought is casual, or only through mass media. Other effects will be taken up in a subsequent section. In order to clarify what is at stake, however, this section will first discuss the effects which may be closest to the mind of the serious newspaper reader who is otherwise unacquainted with economics. That serious newspaper reader probably associates Federal spending with increased output (GNP) and employment, and prob-

Reproduced from Hack, David Bruce. Space program benefits. In Congressional Research Service. United States Civilian Space Programs: 1958-1978; report prepared for the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives. Volume 1. Washington, For sale by the Supt. of Docs., G.P.O. 1983. p. 975-999.

ably associates these in turn with thoughts of higher rates of price increase, and perhaps also with higher money interest rates.

The loose association between aggregate demand and price increases (including interest rates) is a subject of intense and detailed study by economists. While all the details and mechanisms are certainly not agreed upon, almost all economists would agree that increased aggregate demand arising from Federal spending, somehow defined, is in at least a general and qualitative way associated with aggregate price increases. The specifics, and questions about the strength, of this relationship tend to become very complex, and are usually left out of news media accounts. NASA, which like all agencies must annually defend its budget requests before Congress, has been led to commission a detailed study of how the NASA R&D budget *specifically* affects national income and output (GNP), employment, and price increases (inflation). This study was done by Chase Econometrics Inc.[1]

In section 2 of the cited Chase study, the problem definition suggested above is sharpened considerably. Perhaps most importantly, the problem is defined as a forecast of short-run changes in output, employment and inflation arising from NASA R&D funding-rate changes of $1 billion annually, within a context of an unchanged total Federal budget. Chase shows that a very small and *beneficial* result, comes from a shift. The General Accounting Office, at congressional request, reviewed the entire Chase report.[2]

The GAO report dispensed quickly with the Keynesian-type short-run demand effect analysis of the Chase report, section 2:

> The results in section 2 are, in our judgment, reasonable estimates, in accord with widely accepted economic analysis. These effects are small, however, and they are not "benefits" in the strictest sense. Rather, they are measures of induced increases in the level of economic activity. As such, they are not crucial to deciding whether more or less money should be spent on NASA R&D, because similar effects could be obtained by other forms of Government spending—such as defense procurement or energy R&D. Tax cuts are, of course, a comparable alternative, although the size of their impact may differ. Because the results in section 2 are not particularly controversial or critical to budgetary decisions, we do not discuss them further in this report.[3]

In the Chase report "Conclusions," on page 34, Chase concludes as follows:

> In this section of the study, we have shown that a shift to NASA expenditures from other Federal Government spending will stimulate the economy without raising prices.

In view of the extremely small effects calculated by Chase, for a shift to NASA expenditures from other Government expenditures, the phrase "will stimulate the economy," though not qualitatively incorrect, may be quantitatively unimportant. Rather than suggesting that a good argument exists for making such a shift, the figures Chase presents suggest that budgetary shifts between NASA spending and general Federal spending should be made, if at all, on the basis of other and more important criteria, if such exist. On the other hand, the

---

[1] The Economic Impact of NASA R&D Spending. (Prepared for the National Aeronautics and Space Administration under contract number NASW-2741 by Michael A. Evans) Chase Econometrics Associates, Inc. Bala Cynwyd, Pennsylvania. April, 1976. 121 pp.

[2] U.S. General Accounting Office. NASA Report May Overstate the Economic Benefits of Research and Development Spending. Washington, Oct. 18, 1977. 26 pp.

[3] Ibid., p. 3.

figures presented by Chase are even-handed in the following important way: taken at face value they imply that the burden of proof for those wishing to shift expenditures away from NASA toward general expenditures, and for those wishing to do the reverse, is about equal. In neither case can a good argument be made on the basis of short-run general economic effects.

C. Supply Effects—Research on the Aggregate GNP Supply Effect of NASA Expenditures

The Chase report goes on, in section 3, to analyze the more long-run effects on aggregate GNP resulting from changes in the aggregate supply, or the aggregate productive capacity of the economy, as a result of NASA R&D expenditure. An earlier analysis, having some similarity to the long-run analysis by Chase in section 3, was done by Midwest Research Institute.[4] The General Accounting Office report commented on the Chase study alone.

In the Digest of the GAO report, the GAO commented on the Chase report as a whole, drawing a distinction between the short-run demand analysis in section 2 and the long-run supply analysis in section 3. The General Accounting Office evaluated the Chase study as a whole as follows (excerpting here from the Digest of the GAO report).

> The Chase study does not prove convincingly that the benefits are as large as stated. The study is useful as exploratory research, but other types of studies are necessary to provide a complete evaluation of NASA research and development.
>
> The most significant conclusion of the Chase study is that "* * * a $1 billion sustained increase in NASA R&D spending will raise real GNP $23 billion by 1984 * * *." Of this estimated increase, $21 billion would result from improved technology and productivity, and the rest would result from increased Government spending, which stimulates spending in different parts of the economy.
>
> Since similar increases would result from Government spending on other projects, such as welfare programs, the "multiplier effects" [the "short-run demand effects"] alone do not justify more NASA research and development spending. For this reason, GAO focused on projected technological improvements.
>
> The Chase conclusions are questionable from three points of view:
>
> The results, even if accepted as accurate, do not provide the type of information needed to determine whether NASA's spending should increase or decrease. The estimates are of average, rather than incremental effects. Therefore they do not show whether more spending for research and development would result in as many benefits as before. Within NASA's budget, the most productive or unproductive projects or types of spending have not been spelled out.
>
> Even if the Chase approach is accepted, the techniques used had certain shortcomings. Plausible and seemingly minor changes in the study's assumptions lead to major changes in the results. Under some of these alternatives, NASA research and development seemed to have no great effect on productivity. Such sensitivity to small changes in methodology indicates considerable uncertainty in Chase's results.
>
> Basically, the results depend upon statistical correlation between NASA research and development spending and changes in a measure of gross productivity in the U.S. economy. No information on specific NASA projects or on the adoption of new techniques by private business is used in the study. Because of problems in measuring total productivity in the economy and because other

[4] Economic Impact of Stimulated Technological Activity. (Prepared for the National Aeronautics and Space Administration by Midwest Research Institute under Contract NASW-2030, Final Report.) Oct. 15, 1971. Summary Volume, 46 pp. Part I, "Overall Economic Impact of Technological Progress: Its Measurement," 61 pp. and appendixes; Part II, "Technological Progress and Commercialization of Communications Satellites," 130 pp.; Part III, "Knowledge Additions and Earth Links from Space Crew Systems," 81 pp.; and "Bibliography," 81 pp.

possible causes of technological progress were ignored, the correlations may not indicate a true cause-and-effect relationship.

Although the methodology of the particular study may be questioned, the importance of evaluating NASA's programs is undiminished. NASA has clearly been an important source of technical progress in recent years.

Section 3 of the Chase study, and part 1 of the earlier Midwest Research Institute study, both tackle a very similar problem. Both use somewhat similar economic theories.

Both Chase and Midwest Research Institute (MRI) base these portions of their studies on what economists call a production function. A production function is a mathematical equation which relates economic output, or the rate of change of economic output, to the levels or the rates of change of factor inputs such as labor and capital—and, in addition, to a variable representing technology, or the rate at which the available technology level changes. Both Chase and MRI use a production function to estimate economic gains or the increases in gross national product which arise from changes in the level of technology used. Changes in output which cannot be attributed to changes in the amounts of labor and capital available are attributed to the changes in the technology level, and this amount of otherwise-unattributed output change is referred to as a residual. Then, statistical techniques are used to estimate which of several plausible causes of the residual (that is variables which on theoretical grounds might cause gains in technology) are in fact responsible for the gains. Among the causal variables tested by either Chase or MRI is the expenditure on research and development made over the period by NASA (Chase) or by the total U.S. economy (MRI). Other variables are: the education level of the work force, and the age mix and the sex mix of the work force.

Both Chase and MRI recognize that most of the causes of technology change do not act all at once, but that technology changes occur only over a large number of years following a given R&D expenditure, or other cause. Chase bases its estimates of the lengths of these lags in part on the "17th Annual McGraw-Hill Survey of Business Plans for New Plants and Equipment."[5] Chase and MRI compute substantially different lengths of lag for the relationship between R&D expenditures and the GNP supply gained as a consequence of those expenditures.

In the MRI study, gains from research and development are spread over an 18-year period following the time of the particular R&D expenditure—although most of the gains are achieved by the end of about 12 years. Chase, on the other hand, estimates that the benefits in GNP supply begin to be seen in the fifth year, and increase each year to the tenth year following a given R&D expenditure. Thereafter, Chase treats the benefits as accumulating indefinitely at a constant rate. MRI based its estimates of the lengths-of-lags in part on "The Annual McGraw-Hill Research and Development Survey."[6] A discounted rate of return arising from the stream of additional GNP as a consequence of research and development expenditures, is estimated by both Chase and MRI. MRI estimates a discounted rate of return to R&D expenditures of 33 percent, as a consequence of a discounted 18-

[5] Chase. Op. cit., p. 81.
[6] Midwest Research Institute. Op. cit., Part I, p. 41.

year stream of benefits. Chase presents various equation estimates which fall within the range of 20 to 43 percent discounted rate of return, as a consequence of a discounted indefinite stream of benefits. Although the two study results fall approximately within the same range, they should not be regarded as fully conclusive, for reasons among which are those offered by the GAO in its review of the Chase study.

The GAO noted that under some equation forms it was not possible to determine that the returns to R&D expenditures were in fact statistically significant, and therefore some doubt remains about whether the Chase results (and the MRI results) are fully reliable.

The point at issue here is how much of the residual gain in GNP supply arises from NASA R&D, from other R&D, or from other effects which would take place in the absence of R&D expenditures of any kind—such as changes in the educational level, the age mix or the sex mix of the work force. The care with which these variables are chosen, and the exact form in which they are entered in the equation and tested, may make a very substantial difference in both the magnitude of the gains seen to arise from each particular variable, and in the extent to which the estimates of those gains may be regarded as statistically conclusive. MRI estimated that each dollar spent on R&D in general returns slightly over seven dollars in technologically induced economic gains over an 18-year period following the expenditure. Then MRI assumed that the gains over a similar 18-year period, from each dollar spent on R&D by NASA, would have a similar return; that is, seven dollars gained for one dollar expended. However, MRI indicated that:

> There is strong preliminary evidence that the exacting demands of the space program may produce greater than average economic effects due to increased technological leverage. This comes about because NASA allocates its R&D dollar to the more technologically intensive segments of the industrial sector of the economy. The weighted average technological index . . . of the industries which perform research for NASA is 2.1, while the multiplier for all manufacturing is 1.4. Although there are a number of conceptual and procedural limitations to the construction of industry-level technological multipliers, the spread seems large enough to support the view that highly technological undertakings, such as the space program, do exert disproportionate weight toward increased national productivity.[1]

Thus MRI claims that allocation of NASA expenditures to the more technologically advanced industrial sectors means that there may be greater than average returns from the NASA expenditures on R&D. This argument seems to go against the widely applicable economic result that the marginal returns to a single factor of production decrease when that factor is used in increasingly large proportion to other factors of production. Since MRI has chosen to regard technology as a factor of production, one might be led to the opposite conclusion. That is, insofar as NASA R&D increases the technology level of industries whose technology level is already high, the returns to increases in the technology "factor" might in these industries be lower than the returns to the technology factor in the aggregate economy. This matter could use further clarification.

The Chase study indicates that for each dollar expended on research and development by NASA the economy gains productivity begin-

[1] Midwest Research Institute. Op. cit. Summary Volume. p. 10.

ning in the fifth year, such that in the tenth year after the expenditure, and every year thereafter, 4.26 dollars of production are gained. Chase computes that this stream of benefits is equivalent to a 43 percent real rate of return. The difference in distribution over time of the Chase and the MRI streams of estimated benefits affects the extent to which the benefits are discounted. This may account for the similarity in the discounted rate of return estimated by MRI to that estimated by Chase, even though the total returns and the length of time over which the returns are distributed, are substantially different.

The short-run impact of shifting Federal expenditures by one billion dollars to NASA R&D from all other Government expenditures has been computed in the Chase study and has been found to be about nil. In the long-run productivity analysis, MRI performs no analogous calculation for NASA R&D compared to other Government R&D but instead assumes the effect of both NASA R&D and other Government R&D to be equal to that of all R&D, public and private. Neither Chase nor MRI performed any calculation to estimate differences between the returns to NASA R&D and the returns to other Government R&D. The calculation performed by Chase showed only that the short-run impact of shifting Federal expenditures between NASA R&D and all other Government expenditures is practically zero. It did not show what the result would be if the long-run returns to NASA R&D were compared with alternate expenditures for other Government R&D, such as Department of Defense R&D, or Energy R&D.

D. Case Studies of the Benefits of NASA-Developed Technologies

The MRI report goes on in part II and in part III to examine case studies. That is, to supplement the aggregate productivity analysis of part I, MRI examines in part II, "Technological Progress and Commercialization of Communications Satellites," and in part III, "Knowledge Additions and Earth Links from Space Crew Systems." The General Accounting Office, in its review of the Chase study, made the following recommendation to the administrator of NASA.

> Future evaluation studies should look at specific innovations, their effect on specific industries, and the process by which NASA expenditures for research and development improve productivity in the economy. In other words, some of the more important innovations, rather than the total budget, could be examined, and individual technological improvements in individual industries, rather than gross national product figures, could be studied. GAO believes that such studies would give the Congress a more accurate picture of what taxpayers are getting for their money.[8]

It is probably useful, GAO declares, to do micro studies as well as macro studies. That is, it is probably useful to examine some of the more important innovations and individual technological improvements in individual industries as well as to examine the impact of the total NASA R&D budget on gross national product figures alone. This

[8] General Accounting Office. Op. cit., p. iii. At the time of this writing, it is known that NASA initiated, in October 1978, a study by the Bureau of Labor Statistics, U.S. Department of Labor, as a response to this specific critique by the GAO. The study is expected to be conducted over about a two-year period.

does not mean that the GAO report must be read as concluding that further work should not be initiated and completed on aggregate productivity studies. As MRI suggested in its report, aggregate productivity studies and case studies of individual technological improvements arising from individual NASA programs may complement and perhaps reinforce one another. The first MRI case study is described next.

1. Commercialization of Communications Satellites (Midwest Research Institute)

In introducing its first case study in part II of its report, MRI commented as follows.

> [T]he technology application process, by which the economic effects measured in part I come about, almost defies an organized, comprehensive treatment. But some appreciation of the application process and its complexity is necessary if we are to insure a continuing flow of economic benefits from technological progress and avoid the widely discussed penalties of such progress. Faced with this situation the present researchers chose to undertake a case study of a significant technological endeavor, the intent being to illustrate—with specific examples—significant facets of the process, something of its pervasiveness, the kinds of contributions a national R&D agency, like NASA, makes to the process, and the several types of economic applications which flow from or are accelerated by such a technological undertaking.
>
> Since communication via satellite is clearly an example of technological progress made during the last decade and a half, an examination of the R&D effort culminating in this commercial application was selected for case study. In addition, communication via satellite is the first major direct commercialization of technology to result from the national space program.
>
> Part II had two segments: the first being an examination of the technological requirements which had to be satisfied before the several types of communication by satellite could be achieved, an examination of the national R&D program which has and is leading to the satisfaction of the requirements, and the technical contributions of and roles played by NASA in this R&D process; the second being an examination of ways in which participants (NASA contractors) in the NASA portion of the R&D effort . . . have applied the technological capabilities they acquired or augmented during the R&D phase in the resulting *commercial* communication by satellite market and other markets.[9]

a. *Study Plan.*—The MRI report indicates that the major research steps undertaken in connection with satellite communication were to examine the several categories of services which could be provided by communication satellites, and to group these services into four broad types for subsequent investigation. The types selected were: *International*, such as Intelsat/Comsat; *Broadcast Distribution*, such as transmission via satellite to major centers with transmission to ultimate users via conventional terrestrial links; *Direct*, such as transmission to many users direct from the satellite; and *Mobile*, communication via satellite with mobile users, such as in air traffic control. MRI then indicates that the research procedure followed in this case study was to delineate the major technical characteristics or requirements associated with each of the four types of applications.

MRI examined the contributions which NASA programs—particularly SYNCOM and ATS—have made to the satisfaction of the requirements. Then MRI estimated the economic impact associated with the four types of applications. Finally MRI identified and interviewed

[9] Midwest Research Institute, Op. cit. Summary Volume. pp. 12–13.

a representative set of contractors that participated in the SYNCOM and ATS programs to identify the extent and ways in which they participated in the commercialization of satellite communications, and in the indirect application of the technological capabilities they accumulated during their participation in this facet of the space program.

MRI indicates that at least 277 firms participated as prime contractors in the communications aspect of NASA's SYNCOM and ATS programs. MRI selected 14 of these following an intensive sample selection process. This was done because of the need to obtain as representative a cross section of participating companies as possible—that is, large and small firms, satellite and ground stations contractors, aggressive and not so aggressive firms, and so on. Two additional firms which were not prime NASA contractors were added to the sample. One was a direct spin-off from one of the prime contractors. The other was a newly formed company that utilized satellite communications technology in a rather unusual way to assemble and market a marine navigational system.

b. *Commercial Achievements.*—The first satellite commercialization was in the *international* system, which came in the form of the INTELSAT Consortium of which the Comsat corporation is the U.S. partner. Service began in 1965, and when the MRI report was published in 1971, plans called for service to almost 60 nations by 1974.[10] The MRI case study on commercialization of communications satellites indicates that the first domestic *broadcast distribution* system was to be the Canadian Telesat system scheduled for operation in 1973.[11] In the United States, eight applications to provide various mixes of domestic service were pending before the Federal Communications Commission by 1971. There were no commercial plans as yet for direct domestic systems in 1971, although a demonstration experiment for such a system in India was then planned for 1974.[12] The first all-commercial system of the *mobile* type was planned to be in air traffic control and navigation. A prototype system for trans-Atlantic flights was planned for 1975, with service over the Pacific to follow a year later.[13] The MRI case study continues by summarizing the technological history of communications satellites research and development, placing particular emphasis on the following projects: the ECHO Project—a passive communications satellite, TELESTAR and RELAY—medium altitude active repeater satellites, and the ADVENT, SYNCOM and ATS programs—synchronous communications satellites.

---

[10] By 1979 this system had grown to serve 102 nations.

[11] Canada was the first country to establish a domestic communications system with geostationary spacecraft. The Telesat Corporation, acting for Canadian telephone and television systems, launched three Anik satellites—in 1972, 1973 and 1975. Telesat constructed a network of 50 ground stations and developed an annual operating revenue of $28 million. Service is provided at prices competitive with a well established microwave network, and "uniquely throughout the Far North." Space, A Resource for Earth. New York, American Institute of Aeronautics and Astronautics. April 1977. 67 p. (p. 7)

World-Wide Space Activities [Report prepared for the Subcommittee on Space Science and Applications by the Science Policy Research Division, Congressional Research Service, Library of Congress], 95th Congress, first session. Washington, U.S. Govt. Print. Off. September 1977. 607 p. ("Canada," p. 107–109).

[12] The Satellite Instructional Television Experiment (SITE), a joint program involving the United States and India, was conducted from mid-1975 to mid-1976. U.S. Congress. Op. cit., p. 120–121.

[13] This system (AEROSAT) was later cancelled, after publication of the MRI report. Neither the Atlantic nor the Pacific has an air traffic control satellite communications system as of 1979.

The purpose of the MRI historical review was to illuminate some of the key technical developments that led, cumulatively, to our present knowledge and capability in the communications satellite field. The review demonstrated that practical progress has occurred across a broad technological front. This was illustrated by the fact that by 1971 a commercial communication satellite system had been in operation for six years, while only slightly more than ten years prior to 1971 many experts had serious doubt that satellites could be placed in synchronous orbit before 1970, that satellities could survive in space and operate long enough to be economically viable, that the quality of satellite communications transmission would be acceptable, and that the cost of satellite systems would be competitive with traditional earth-based communications.

c. *Further Technical Benefits.*—The MRI case study goes on to say that the public often fails to grasp the multiplicity of roles which Government R. & D. agencies play in the technological progress processes. MRI indicates that only in instances where the complete NASA-developed systems are commercially applied as a whole package, is the link to the space program readily apparent. Such clear-cut transfers do occasionally occur, said the MRI case study. For example, MRI cited NASA SYNCOM III, saying that it became the commercial INTELSAT I, but MRI indicated that such direct commercializations of an entire system are rare. More subtle relationships are more often the rule. Less obvious roles played by NASA in the development and commercial applications of technology, as cited by MRI, include the following:

Conducting In-House Research.—MRI gives, as an example of NASA in-house research contributing to commercial applications, the mechanically despun antenna used in INTELSAT. The initial idea came from Kampinsky's laboratory group at Goddard Space Flight Center. Subsequently, Sylvania laboratories did the actual design and fabrication with key assistance from Ball Brothers, Kearfott, and Mechanical Technology, Inc. Antenna performance was validated on ATS III and after additional work Intelsat incorporated the mechanically despun antenna in its third generation of satellites.

Generation of New Knowledge and Understanding.—MRI indicated that this is achieved by the performance of scientific experiments which provide the basis for technological improvements. The findings of the Earth's triaxiality and the mapping and location of "graviation grave yards" underlay the selection of positions for geostationary satellites so that they might be maintained on station much longer than their station keeping expendable supplies would otherwise permit.

Classic Request for Proposal Process.—MRI indicated that in this process application requirements are defined, technical planning is undertaken, and these needs are made known in research organizations and the industrial community through the procurement process. This is a traditional and well established way of motivating innovations which often advance the state of the art.

Initial User or Initial Adopter.—MRI indicates that: given knowledge of NASA mission and technical requirements, aggressive firms often undertake developments in anticipation of marketing the results to NASA. Cassegrain feed systems, for example, received early impetus

via this role and are now the standard approach for large ground stations. Suppliers now enjoy the Intelsat market.

Alternative Evaluation.—There are almost always alternative technical paths, MRI indicated, by which a requirement can be satisfied. NASA in its role as an R&D agency has provided the wherewithal for exploring the competitive advantages of alternatives. Tests of cryogenic masers versus cooled parametric amplifiers are a case in point.

Demonstration to Acquire Confidence.—MRI indicated that an important aspect of technological progress is the reduction of uncertainty. NASA flight programs have made many contributions of this type through the accumulation of operating confidence and predictability.

d. *Selected Commercial Investment Figures.*—MRI provided indicators of the present and future economic impact of the development of communications satellite technology and its application in the commercial sphere. For example, MRI compared early estimates of the cost of communications by satellite with the dramatic cost declines actually experienced as the technology evolved. MRI noted that the reductions in cost are striking and that similar cost declines have been experienced in Earth station costs. MRI noted that because satellite communication offers both service advantages and cost advantages over preexisting means of communication, growth in the international application has been dramatic, and MRI provided examples. MRI indicated that in spite of the rapid growth of the *international* application, the economic impact of domestic *broadcast distribution* would be much greater. The total overseas telephone and telegraph traffic, MRI indicated, was on the order of 50 million messages per year, while over 8 billion domestic long-distance messages are carried annually.

MRI indicated that in 1971 a total of eight applications for domestic satellite networks were pending before the Federal Communications Commission. The proposed initial investment ranged from about 100 million dollars to over one-quarter billion dollars. MRI noted that several of the applicants had pledged to have their systems in full operation in less than three years after FCC approval.

In Canada, a $90 million domestic system was planned to be in full operation by mid-1973. The bulk of the equipment was to be supplied by U.S. firms.[14]

MRI said that the first commercial *mobile* application would be an aeronautical satellite system providing communication links for transoceanic airline flights. Expectations as of 1971 were for an investment in the $125 million to $150 million range for a two-ocean system by 1977.[15]

e. *Indirect Economic Impact.*—The MRI case study on commercialized satellite communications indicated that most of the firms that performed substantial technical work in developing or experimenting with the NASA communications satellite systems were themselves affected in a variety of ways—some organizations to a greater extent than others. MRI made the following flat statement in summarizing the indirect economic impact on aerospace contractors:

---

[14] The $90 million figure appears to be an investment estimate. Annual revenues had risen to $28 million by 1977. American Institute of Aeronautics and Astronautics. Op. cit., p. 7.

[15] These investments were cancelled. There is no satellite system providing communication links for transoceanic airline flights, as of 1979.

Conceivably the most significant finding from the study of these contractors is simply that *every firm interviewed* indicated that their performance of space communications work had produced some residual economic effect. Not all effects were easily identifiable, but the challenge of high technology and the response by the company was stated to have influenced the firm or "left its characteristic mark." [16]

MRI said that the lasting consequences identified fell broadly into three classes or types of influences. First there were internal effects on the firms. Some firms modified their processes and procedures, the internal structure of the division, the way they operated, their management systems, tighter quality control; or perhaps introduced new procurement policies or more efficient production methods. "Economic effects from these internal changes are usually known as efficiency or increased productivity," according to the MRI case study.

Second, in addition to the internal effects, the majority of firms studied found ways to utilize the knowledge, expertise, and product capabilities that were augmented through NASA satellite work to establish or to strengthen their position in supplying the needs of commercial satellite systems. However, according to MRI, much more was involved than a simple decision to sell satellite systems to another customer.

Procedural as well as technological changes are also required as part of the changeover effort needed to sell to new markets or to commercial users having non-NASA requirements. But all contractors interviewed felt that the economic rewards derived from switching over to commercial sales were worth the efforts.

The third effect on NASA contractors was that some firms utilized new knowledge, experience, and heightened perception of changing market needs, to transfer emerging or developed skills into new non-space markets. New ventures, new services, non-governmental markets needing similar skills, and most of what has traditionally been called "spin-off" was found in this category of company effects. The economic effects are hardest to trace here. Seldom was there a direct one-to-one transfer; more commonly the transfer was feasible only because the contractor suddenly perceived that a need, a technology and a market were approaching conjunction.

MRI stated that technological change does not occur spontaneously people have to make it happen. The "internalized costs" of innovation are not trivial. These costs include (1) the cost of acquiring new knowledge—about market needs, about external situations, and about the availability of new technology; (2) the cost of learning to apply this new knowledge to the satisfaction of economic wants—education and training of production and marketing personnel, feasibility demonstrations and trial marketing; (3) the "changeover" costs (obsolescence and sunk costs) of abandoning old ways and adopting new ways of performing the firm's economic function.

MRI said that recent scholarly studies of innovation had unmistakably shown that the force that induces industrial innovation is the economic pull of the marketplace, not primarily the forward thrust of new technology.[17] The costs and barriers that impede the adoption

[16] Midwest Research Institute. Op. cit. Summary Volume, p. 26. Emphasis in the original.
[17] Midwest Research Institute. Op. cit. Summary Volume. p. 27. Part I, p. 122. See also Bibliography, pp. 12–31.

of new technology (such as those cited above), are never easy to surmount. Within large organizations possessing considerable inertia, powerful forces are necessary for the successful introduction of any innovation.

MRI summarized the case study of commercialization of communications satellites in the following words:

> Yet the fact is that innovation does occur, regularly—in both large and small companies. Firms do learn, adopt new techniques, improve designs and enter new markets—because technical change and innovation offers handsome economic benefits. A number of specific examples of this economic force at work were found during the survey of sample contractors.[18]

MRI illustrated the above statement by providing an extensive list of individual companies which had reported to MRI on benefits which those companies had experienced.[19]

2. Technical Change Effects of Environmental Satellites (NOAA)

The section just above discussed the technological progress arising from commercialization of communications satellites. This is a primary application of NASA-developed technology. The second case study also involves a primary application of NASA-developed technology. The second case study presented in this section is a summary of the economic benefits of environmental satellites. The documentary source of this case study was published by the National Oceanic and Atmospheric Administration (NOAA) of the U.S. Department of Commerce.[20]

NOAA environmental satellites are used on a continuous basis to monitor the weather and weather-related phenomena around the world, especially in the western hemisphere. The technology for this Commerce Department program was developed, and its feasibility demonstrated, by NASA. The NOAA document cited indicates that two prototype satellites were launched by NASA on May 17, 1974 and February 6, 1975. Two NOAA-funded satellites were launched October 16, 1975 and June 16, 1977. All of these four satellites were operational in 1978; two were being used regularly and two others were in orbit on standby duty. Each of these four satellites is a geostationary satellite—meaning that it circles the Earth once each twenty-four hours and thereby remains in a fixed location over the Earth's surface. NASA has also developed, and NOAA is using, polar orbiting satellites which sweep around the Earth from South Pole to North Pole as the Earth rotates beneath the orbit. In 1978 the operational NOAA polar orbiting satellite was NOAA–5, which was launched in 1976. This satellite and others in its series were scheduled to be phased out in 1978, in this rapidly developing technology, and replaced by a new third-generation series of operational polar orbiting satellites.[21] In the following section the technological benefits which the spacecraft of the National Environmental Satellite Service have brought to industrial and commercial activities and to operations of the Government are discussed.

[20] U.S. Department of Commerce. National Oceanic and Atmospheric Administration. National Environmental Satellite Service. The Economic Benefits of Environmental Satellites (by W. John Hussey and E. Larry Heacock). April 1978. 33 pp. Presented at the Fourth Annual Convention of the Eastern Economic Association on April 27, 1978, Washington, D.C.
[21] NOAA–5 is still in operation (May 1979). The first TIROS N prototype (successor to the NOAA series) was launched in 1978. The TIROS system is still experimental.

a. *Some Estimated Dollar Benefits.* Satellite data have assisted ships at sea to save fuel by plotting navigational courses to take advantage of ocean currents. They have helped the Florida citrus industry save fuel, which would otherwise be used to heat Florida citrus groves on cold winter nights. Satellite weather data have helped the Hawaiian sugar cane industry plan its harvest, and avoid crop losses due to unforeseen weather conditions. Satellite weather data have helped to pinpoint the location of rough weather conditions where general aviation aircraft have been lost. As a consequence a substantially reduced amount of flying time is required to locate lost aircraft, with consequent fuel and other savings. Satellite weather data have helped to extend the shipping season in the Arctic Ocean and the Great Lakes. Satellite weather data have helped farmers plan agricultural operations which are weather-dependent. NOAA satellites are able to map snow cover over land areas, and to predict flooding from prospective snow-melt conditions. Satellite-based infrared imagery can depict the location of thermal boundaries or "fronts" on the ocean surface. It is known that certain species of fish such as blue fin tuna and salmon tend to congregate in temperature-specific regions of the ocean, and these temperature-specific regions of the ocean can be located through satellite infrared imagery. This has helped the fishing industry use less fuel while at sea, as well as to increase the catch. NOAA satellites provide environmental data to forecasters and Government officials regarding tornadoes, severe thunderstorms, hurricanes, tropical storms, flooding, severe winter storms, and other less destructive environmental phenomena. Satellite data are transmitted 24 hours per day, 7 days per week to the various national centers for environmental warning. Satellite imagery is used extensively in monitoring tropical storms and hurricanes.

The cited NOAA document states the following:

> Since the inauguration of the operational satellite system, no tropical storm goes undetected, even in the most remote areas of the world. Hurricane reconnaissance aircraft no longer have to fly random search patterns over the tropical oceans to locate storms which may be brewing there. Estimated savings for using satellite storm detection and monitoring in mid-ocean in place of expensive aircraft reconnaissance are about $1.8 million annually.
>
> • • • • • • •
>
> A 1975 NOAA Technical Memorandum . . . noted that until 1974, the initial position error for storms within 500 [nautical] miles of the coast averaged 22 [nautical] miles, and landfall forecasts were made from distances no more than 300 [nautical] miles. A positioning error is defined as the difference between the forecaster's assumed initial position of a storm and the actual position as determined from a post-analysis.
>
> The issuance of hurricane warnings along a portion of the United States coast line is generally accomplished 18 to 24 hours prior to the expected arrival of the storm at the coast. This particular time interval has been found to be an optimized trade-off between the desire to provide maximum warning lead time and the ability to keep the size of the warning area within reasonable limits. With such a lead time, the length of the warning zone averages nearly 300 [nautical] miles. Inasmuch as the swath of damaging winds is generally less than 100 [nautical] miles, the public must expect a minimum overwarning area of about 200 [nautical] miles.
>
> A 20% increase in the size of a hurricane warning zone can be expected if the currently observed positioning errors are increased an average of 10 [nautical] miles. However, a 10 [nautical] mile decrease in positioning area yields only an 11% decrease in the size of the warning area.
>
> • • • • • • •

It is estimated that protection costs (including losses due to temporarily curtailed production) for a typical 300 [nautical] mile Gulf of Mexico coastal hurricane warning zone total $25.1 million. A 10 [nautical] mile increase in positioning error will thus increase this economic loss by about $5 million per storm. A 10 [nautical] mile decrease in positioning error will decrease protection costs by about $2.75 million per storm.

Since an average of about two hurricanes annually move inland on the continental United States, using the above figures, $50.2 million is the average annual cost of protection. As a conservative estimate, a reduction of only 5% in the coastal warning area would mean an average annual savings of about $2.5 million per year. Satellites play a major role in keeping the warning area to a minimum.[23]

b. Unquantifiable Benefits.—In addition to the nine areas named above, in which the National Environmental Satellite Service satellites provide economic benefits which are both tangible and measurable, these satellites also contribute heavily to the National Weather Service's National Meteorological Center, the central weather analysis and prediction facility for the United States. In a 24 hour period, the National Meteorological Center receives about 42,000 conventional weather observations, plus a large volume of satellite observations. The National Meteorological Center synthesizes all types of meteorological data such as satellite, surface, upper air, and radar observations. This results in a more complete and accurate understanding of atmospheric processes.

NOAA, in the 1978 report cited, summarized as follows:

The environmental satellite is an excellent global observational platform and the United States freely contributes data from its satellite to the world meteorological community. Satellite data is an important part of the World Weather Watch Program of the United Nation's World Meteorological Organization. The direct readout systems . . . from the polar orbiting spacecraft and the . . . transmissions from the geostationary spacecraft are extremely useful in as many as 120 countries around the world. A large international project called the Global Atmospheric Research Program is underway in which satellites play a primary role in gathering atmospheric data on a global scale.[24]

Thus, environmental satellites contribute significantly to large scale or global weather observation and forecasting, but it is impossible to derive an actual cost benefit in annual dollars saved. To obtain the quantity and coverage of data which the satellites provide by more conventional observation methods such as surface observations, radiosonde, radar, meteorological buoys, etc. would not only be prohibitive from the cost standpoint, but it would be essentially physically impossible. The value of satellite input to global scale observations is certainly in the many millions of dollars.[25]

c. Environmental Satellite Benefits Summarized.—The National Environmental Satellite Service summarized the estimated annual savings from the nine categories discussed above in which annual savings estimates were possible. The fuel savings in Gulf Stream navigation arising from helping ships steer into currents going their way, and steer away from currents going against them, is estimated to be $360,000 annually by the EXXON Corporation alone. The Florida citrus industry is estimated to save $48,000,000 annually, assuming an average year in which there are 35 "cold" nights per year—that is, nights in which heating of groves is required. In the Hawaiian sugar cane industry the estimated annual savings of crop losses is $1,000,000 for

[23] U.S. Department of Commerce. Op. cit. pp. 20–22.
[24] The Global Atmospheric Research Program (GARP) has been continued, and will be continued at least through Dec. 31, 1979.
[25] Ibid., p. 27.

the Waialua Sugar Company only. In search and rescue, it is estimated that $7,300,000 are saved due to reduced flying time by the United States Air Force Aerospace Rescue and Recovery Service, and the California Wing of the Civil Air Patrol, because pinpointed weather conditions permit downed aircraft to be located in a matter of about 48 hours instead of approximately a week. It is estimated that the Arctic and Great Lakes ice monitoring saves $35,000,000 by extending the shipping season on the Great Lakes 30 days annually. The General Agriculture Industry is estimated to save $74,000,000 annually, as a consequence of satellite weather data. The snow cover mapping capability of NOAA satellites is estimated to save about $100,000 in flying time for snow cover mapping of the Sierra-Nevada Basin alone. In the West Coast fishing industry it is estimated that the savings in fuel by ships at sea while locating schools of fish, plus the value of the increased catch of fish, is $2,440,000 annually, for the albacore and salmon fishing industries only. For disaster warnings, it is estimated that $4,300,000 worth of economic production is saved annually due to improved hurricane warnings only. Finally, in large-scale weather forecasting, NOAA regards it as impossible to estimate a dollar savings. The dollar savings here is regarded as unknown but considerable. The total estimated annual savings for the nine categories in which estimates have been made is $172,500,000. The National Environmental Satellite Service document from which these figures are taken indicates that the total National Environmental Satellite Service budget for FY 1978 was $94,300,000, or about half the cost savings arising from these few selected areas.

3. Secondary Effects—Gross Technical Change Effects By Industry (Mathematica)

The first set of case studies of secondary effects of NASA-generated technology have been described by Mathematica, Incorporated, under NASA contract.[25]

Mathematica stated that the most widely accepted principle for evaluating economic benefits is founded on individual "willingness to pay" to move from a "less" to a "more" preferred state.[26] Mathematica says that what this principle translates into for the purposes here is that the benefits of technological change can be measured as the cost savings generated by new or improved production processes, plus the extra value that consumers attach to new or improved final products. (An economist might describe this as being the sum of the changes in the producer profits and the consumers' surplus as a result of technological change.) Mathematica says that by determining how cost and demand for various products are affected by specific technological advances, one can estimate the benefits of these advances.

Further describing its methods, Mathematica indicates that the research process by which technological advantages are generated typically involves a complex interaction of various groups and individuals. In solving the particular problems associated with an advance, the

[25] Quantifying the Benefits to the National Economy from Secondary Applications of NASA Technology. (Prepared for the National Aeronautics and Space Administration by Mathematica, Incorporated), Princeton, N.J., June 30, 1975. 176 pp. Executive Summary. 10 pp.

[26] Mathematica. Op. cit. Executive Summary. p. 3.

individual research "actors" build up or combine their results with those generated by others. The "credit" for the benefits created by a particular advance should, in a real sense, be shared by the various contributors.

But it would be helpful to be able to assign a particular share in some specific cases. The method used by Mathematica for assigning the share is based on the premise that NASA R&D led to an earlier realization of the particular technological advances being considered. According to Mathematica, this view of technological advance has been proposed and defended by a number of authors.[27] This view specifically is that had NASA not done its R&D, these technological advances would still have occurred, but at a later date. As a consequence of this, the measurement of benefits attributable to NASA becomes in principle a rather straightforward task. Mathematica concludes that the benefits can be measured as the difference between the present value of two benefit streams: one, the stream resulting from the advance that has occurred, and two, the stream that would have resulted had NASA not been involved. Mathematica questioned technical experts outside the NASA establishment about the speed-up resulting from NASA's role. Of course, their judgements varied. In order to allow for this, the extent to which NASA accelerated the time stream of benefits was calculated based on a minimum, a maximum, and a conservative "probable" speed-up due to NASA. Mathematica did not select areas for study randomly, but deliberately selected cases on which data were available, where NASA's role was widely acknowledged, and where benefits were anticipated to be relatively large. "Consequently, until additional experience with more case studies is acquired, it is not possible to draw inferences regarding the total secondary benefits of NASA's R&D." [28]

Mathematica attempted estimates of secondary benefits from six NASA technological areas, and was able to complete four of these. The others were not completed due to data unavailability.

First, it was estimated that NASA research on jet propulsion had advanced the technology of gas turbine engines by approximately one year, and that this had caused a total cost savings in the electric power generating industry of approximately $111,000,000, as a consequence of higher energy-conversion efficiency.

Second, Mathematica estimated the economic benefits arising from multilayer cryogenic insulation, developed by NASA for use in handling liquefied gases. It was estimated on the basis of a survey of expert or informed opinion that NASA had advanced this technology by approximately five years, and that the benefits accruing to industry from the five-year speed-up of this technology were approximately $1,054,000,000.

Third, Mathematica further estimated that NASA R&D had speeded up the development of integrated circuits by about two years, and that the "probable" benefits arising from use of integrated circuits in all types of electronic products were approximately $5,080,000,000.

Finally, Mathematica estimated the benefits to producers and consumers of a large multipurpose computer program which was devel-

[27] Mathematica, op. cit., p. 17.
[28] Mathematica. Op. cit. Executive Summary. p. 5.

oped with NASA support. This computer program package is called NASTRAN, for *NA*SA *STR*uctural *AN*alysis. This computer software package was designed for static and dynamic analysis of the behavior of elastic structures. It is used principally by general product engineers in mechanical or civil engineering applications, including aircraft and automobile production, bridge construction, and power plant modeling. Estimates of cost savings from the use of NASTRAN were obtained from telephone interviews with a sample of users. From the sample responses "probable" benefits accruing to the population of NASTRAN users were estimated by Mathematica at $701,000,000.

The total of these four estimates of "probable" benefits arising from NASA-developed technology, or technology which NASA research helped to make available earlier, is $6,946,000,000. Mathematica concluded as follows:

- Operational methods can be developed for estimating the secondary benefits of mission oriented R&D.
- Secondary benefits attributable to NASA R&D programs may be impressively large. For example, the $7,000,000,000 total for the four cases studied is more than twice NASA's present yearly budget.
- Because secondary benefits may indeed be significant, public decisions concerning the allocation of resources to research and development programs should, where possible, consider such benefits.[29]

4. Secondary Effects—Earth Links of Space Crew Systems Development (MRI)

Case studies of the secondary effects of NASA-developed technologies are continued here by returning to the Midwest Research Institute report, part III. This case study examines the technological improvements, and suggests economic benefits, arising from the research, development and production of space crew systems—that is, those systems designed to support human life in space, and to enable space crew members to perform work in space. MRI titled this case study "Knowledge Additions and Earth Links from Space Crew Systems."

a. *Why Study Space Crew Systems?*—MRI asserts that the worldwide knowledge bank consists, in simplest terms, of everything known to man. It includes everything from knowledge on basic phenomena to manufacturing "know-how." As the problems addressed become more complex, additions and refinements to the knowledge bank are essential. MRI says that another characteristic of the knowledge bank is that the information in it usually contributes to the solution of problems beyond those visualized by the original developer. Thus, the ultimate utility of any piece of know-how cannot be assessed at the time of its generation.

The means by which the knowledge bank is added to and refined include both basic research, and the efforts of individual innovators faced with very specific problems. Somewhere in between these extremes is so-called mission-oriented research, of which the space program is an example. Since mission-oriented R&D programs typically stretch some aspect of the state of knowledge and ultimately culminate in hardware, they often make broad contributions to the knowledge bank—in the basic and applied sciences, in several engineering fields, in manufacturing processes, in analytical techniques, and so on.

[29] Mathematica. Op. Cit. Executive Summary. p. 10.

MRI stated that it chose to examine the contributions expected of mission oriented R&D by means of a case study of those aspects of the manned space program directly related to human life support and work performance in space. Much of the information needed to design life- and work-supporting systems was not available. Therefore, scientists had to undertake research. Physiologists and others had to become much more precise in their understanding of human life requirements. In many instances, the knowledge available to engineers in their own fields was inadequate for the task at hand—in much the same way that physiologists' knowledge of requirements was lacking. Research was supported to develop data and extend the available engineering knowledge. In many instances, new knowledge was necessary in the manufacturing and testing of the equipment also. New materials were required, tolerances were smaller, reliability had to be higher, and so on.

b. *Study Plan.*—MRI conducted this case study through personal interviews with NASA contractors and NASA laboratory personnel. Several participants in crew systems research and development at each firm or lab were asked:

- What did you have to learn in order to do your part of the manned space program, i.e., what was known and unknown when you began?
- What sort of solutions did you develop and apply?
- How, if any way, does what you learned or what you did relate to Earthly problems? [∞]

c. Nine Space Requirements Linked to Earthbound Issues.—MRI said that ten to twelve illustrations of new or improved knowledge were noted in each hour to hour and one half interview, and most of the knowledge gained had some relationship to needs here on Earth. In total, part III of the MRI report presents over 130 illustrations—indentified during the limited number of interviews—wherein knowledge additions were traceable to the crew systems efforts of the space program.

Part III is arranged in terms of nine requirements which had to be met to maintain man alive and productive in space. The nine requirements are the following: the supply of breathable atmosphere; carbon dioxide removal, and carbon dioxide recycling; contaminant control and removal; maintenance of thermal balance; space hazards—decompression, radiation, meteorites, fire and blast; provision of adequate light and vision; provision of mobility and work capability; provision of adequate habitability. MRI found that in total almost 200 links to down-to-Earth issues were identified. Though not all of the identified links may come to pass, other less obvious linkages may emerge. MRI noted that predicting areas of greatest utility for given pieces of new knowledge has been subject to significant oversights throughout history. Thus the linkages identified by MRI are those which seemed most clear to the authors. They were offered only as indications of ultimate impact.

NASA developed improved heat exchangers which could result on Earth in smaller, quieter heat pumps and air conditioners.

NASA developed heat pipes to transmit metabolic heat through the space suit and into space for temperature control. TRW Systems Division which developed the heat pipes for cooling space suits, has

[∞] Midwest Research Institute. Op. cit. Summary Volume. p. 36.

since granted licenses for the use of this technology for industrial process furnaces. A major use of these furnaces will be the production of semi-conductors, which require extremely uniform heat treatment. Other heat pipe applications range from the processing of jet aircraft turbine blades to cooling nuclear reactors.

NASA developed improved vacuum evaporators with which to purify water. This knowledge adds to the technological base underlying a number of commercial processes which remove water from heat-sensitive products such as instant food products, instant coffee and soups, and dry non-fat milk.

NASA developed a coordination tester to determine the effects of atmospheric contaminants on astronauts' performance. The device permits measurements of hand-eye coordination in several tracking and pursuit tasks, and the influence of toxic materials and fatigue can be determined. This device has been found to be suitable for testing automobile driver coordination and the effects on such coordination of air pollutants, carbon dioxide, carbon monoxide and alcohol.

NASA developed an optical grade polycarbonate sheet plastic for use in space suit helmet faceplates. Earth applications are for safety, riot control and motorcycle faceplates, aircraft windows or canopies, and screens around hockey rinks.

NASA developed an eye motion measurement instrument called an oculometer. The oculometer measures eye movement in carrying out search and discrimination tasks to determine the speed and efficiency with which the eyes process information within the visual field. Persons engaged in activities requiring vigilance and highly developed discrimination can be aided by training based on oculometer data. The oculometer provides real time eye movement tracings which are displayed on a screen. Thus an instructor can coach the pupil in improving eye use. The procedure provides the means of testing concentration and alertness. The oculometer has utility in training air traffic controllers and quality control inspectors, in reading analysis and psychological testing, and for "studying the earlier development of the oculcmeter system in children." [31]

NASA required the development of rubbers and plastics that would not burn in oxygen. The resulting elastomers have the capability for use in a variety of oxygen-rich environments. Anesthesia hoses and masks, interior decorative panels on commercial aircraft, and upholstery coatings in aircraft, are some of the uses of these elastomers.

NASA developed water electrolysis systems capable of furnishing crew oxygen for more than ten-thousand hours. The operation life of previous electrolysis units was typically limited to one-thousand hours. On Earth, at present, there are a number of situations which require that oxygen be stored at high pressure. This is an inherently hazardous procedure. The NASA-developed electrolysis system is being tested for military aircraft, and is under consideration to replace high-pressure oxygen for emergency use by commercial airline crews. The system provides oxygen on demand and does not require storage. Water electrolysis is also being investigated as a source of oxygen for newborn infants. To prevent eye damage the amount of oxygen supplied to the incubator or isolette must be precisely controlled. Present practice is to

[31] Midwest Research Institute. Op. cit. Summary Volume. p. 43.

measure flow rates of the oxygen being delivered from storage tanks. Greater precision can be obtained by water electrolysis generation of oxygen, because oxygen production is directly related to the supply of electrical current to the unit.

The final example which MRI offered in this case study of NASA-developed technology for the support of life in space, and having applications on Earth, was the development of direct whole-body calorimetry. As a consequence of NASA research and development, direct, whole-body calorimetry can now be performed conveniently and accurately on a real-time basis, by recording heat transmitted to liquid cooling garments. Previous techniques were indirect or restricted in the extent of human activity permitted, or had slow response rates which precluded study of thermal transients. On Earth, direct calorimetry is being employed on a number of research topics, including: physiological research on basic body homeothermic and metabolic processes; medical research on fever and antipyretic treatments, on diet—such as the specific dynamic actions of various classes of nutrients; on metabolic disorders—such as thyroid functions; on the various types of shock and the physiological processes involved; on heat exhaustion and sun stroke investigation; in industrial hygiene for the study of workers in hot and cold environments, for the establishment of work standards and practices; and even in the study of athletic stamina and endurance.

Midwest Research Institute concluded the case study of part III in the following words:

> The findings of this study indicate that the long term economic benefits of the space program are much more profound than superficial examinations would indicate, and that the importance of technological progress to national well-being must not be ignored. However, much remains to be learned about the specifics of how technology interacts with the economy. The investigations reported upon in this five volume work were performed within the current state of the art. There is a need to extend and refine our knowledge on many aspects of advancing technology and its economic and social impacts. The present researchers hope that this study will encourage others to seek better understanding of the processes involved and more precise answers to the questions we addressed.[88]

E. How the Case Studies Relate to the Aggregate GNP Supply Effects Analysis

This completes the survey of two broad categories of study, both directed to estimating the economic effects, or the increase in economic productivity, arising from innovation in general, and specifically from innovation promoted by NASA R&D expenditures. The first broad category of productivity analysis was the aggregate economic productivity analysis illustrated by both part I of the Midwest Research Institute study and by section 2 of the Chase Econometric Associates study. The second broad category of technology improvements analysis has been the case studies described just above.

The aggregate productivity analyses have the advantage that they cover the whole economy. They have the disadvantage that, for many readers, they cover the whole economy in a rather too-abstract way. They have the further disadvantage that the details of the methods employed are not entirely agreed upon by Midwest Research Institute and Chase Econometric Associates, nor for that matter are these

[88] Midwest Research Institute. Op. cit. Summary Volume p. 46.

methods fully developed by the economics profession at large. It is encouraging however that NASA, whose primary mission involves research and development in the physical and engineering sciences, has commissioned economic and statistical studies of the economic effects of its activities. These studies were apparently at or near the frontier of relevant economic analytic knowledge as that frontier was known when these studies were commissioned, and when they were completed in 1971 and 1976.

The case studies (in contrast to the aggregate productivity analyses) have the advantage that they lend concreteness to the analysis of technological and economic effects of NASA R&D expenditures. Conversely, they have the disadvantage that they are partial, local and not exhaustive of the full range of NASA benefits, and impacts on the economy at large. The case studies have the further advantage however that they serve to illustrate the processes at the technological level, the innovation level, and the industry level, which are assumed to add up to the aggregate technological improvement, and the aggregate economic benefits, which are estimated in aggregate productivity analysis. The case studies described so far are successful in that they do illustrate in a concrete and down-to-Earth way, some of the mechanisms which are presumed to underlie the aggregate economic estimates.

The General Accounting Office review cited earlier reviewed the Chase study alone, and therefore reviewed no case studies. The General Accounting Office, in its review, made the following recommendation to the administrator of NASA:

> Future evaluation studies should look at specific innovations, their effect on specific industries, and the process by which NASA expenditures for research and development improve productivity in the economy. In other words, some of the more important innovations, rather than the total budget, could be examined, and individual technological improvements in individual industries, rather than gross national product figures, could be studied. GAO believes that such studies would give the Congress a more accurate picture of what taxpayers are getting for their money.[88]

The above GAO recommendation, made in review of a report which included no case studies of the type GAO suggested, may have been appropriate in its context. However, because the two aggregate productivity analyses are about eight years and three years old respectively, and because the case studies are still somewhat scattered, and do not include any studies which use productivity analysis (or production function analysis) at the industry level rather than for the aggregate economy, it appears that both of the two broad categories of analysis described here could be pursued much further—both in parallel and in combination. If NASA-sponsored analysis of the economic effects of R&D were to stop with the documents cited here, NASA might soon fall far behind the frontier of such economic analyses.

F. Case Studies—Regional and/or Industrial Effects Analysis

In addition to the case studies described above, there are at least two documents which might be considered case studies by some definition, but which are extremely limited in any meaning for analysis of a na-

[88] U.S. General Accounting Office. Op. cit. p. iii.

tional R&D program. The Midwest Research Institute study attempted to provide in its part II and part III the beginning of a microeconomic rather than macroeconomic analysis. In addition the GAO recommended, in the context of its review of the Chase study, additional microeconomic or sectoral or industrial analysis—not necessarily as a substitute for, but as a supplement to, macroeconomic analysis such as provided by MRI and by Chase. The microeconomic or sectoral or industrial analyses done so far in supplement to the macroeconomic analysis may require substantial further development. But the needed sectoral analysis is not provided by certain types of sectoral or regional studies, or by studies which are both sectoral and regional simultaneously. The two documents described here originated either in the aerospace industry, or in the aerospace industry press. Both of the documents focus upon a specific region; in both cases, coincidentally, this region is the State of California.[24]

Studies of these kinds have a serious defect, when viewed from a national policymaking perspective. Simply put, they are exclusively concerned with the relationship of the economy in a particular region and/or industry of the United States to the spending by NASA. Studies of such types would perhaps be no less and no more parochial if they originated from any of the other 49 States.

The Rockwell International Report, "Impact of the Space Shuttle Program on the California Economy," is at its heart the same sort of analysis (performed for the State of California) that Chase Econometrics performed in its section 2, with one important exception. The Chase short-run macroeconomic demand study for the national economy analyzed the impact on the economy, in employment and inflation, of a shift of a certain amount of Federal expenditures to NASA R&D from all other Federal budget categories. As was described earlier, Chase computes very small effects from such a shift. The Rockwell report also computes employment and income effects—but for the California economy. The Rockwell paper does not describe a shift of Federal expenditures from one category to another within the State of California. Rather, the Rockwell paper assumes a net increase in Federal contracting and procurement in California as a consequence of the Space Shuttle program. It does not assume that the contracts let in California for Space Shuttle R&D are offset by reductions in Federal spending in any other category in California. Thus one must assume, though the Rockwell report does not say, that the Federal funds for those contracts either are shifted to the California economy from the economy of the other 49 States, or that the funds for the Space Shuttle contracts in California are obtained through increased Federal borrowing (increased Federal deficits).

Whereas the Rockwell paper is concerned only with the direct demand effects on employment and income in a region, the Holman and Konkel paper is concerned with the direct demand effects on a specific industry in that region, namely the aerospace industry in California. Both of these papers are of fully legitimate interest to the residents of California in general and to those employed by the aerospace industry

[24] Impact of the Space Shuttle Program on the California Economy. Space Division. Rockwell International. December 1974. 16 p.
Mary A. Holman and Ronald M. Konkel. "Space Employment in Los Angeles: A Declining Role in the Aerospace Industry?" California Management Review, Fall 1968. pp. 23–30.

in California in particular. They would certainly be of profound interest to almost all elected officials in California, just as similar reports from another State would be of great interest to elected officials of that State. But the short-run employment and income impact analysis of these papers suffers from the same limitations as direct demand analysis at the national level, with the added danger of the "fallacy of composition." To illustrate: if a national policymaker read these two reports, and concluded from them that the added income and employment benefits of added NASA expenditures in California also conferred similar economic benefits upon the rest of the Nation, that national policymaker would have engaged in the fallacy of composition, even though the authors of the Rockwell paper in particular carefully skirt such a conclusion. The authors of the Rockwell paper are careful to exclude the value of subcontracts awarded outside the State, and the purchase of materials from outside the State, from the overall employment multiplier effect which they calculate. So there is no fundamental flaw in the Rockwell paper, as an analysis for California. From a California perspective the Rockwell paper makes the following important point:

> While leakages [out of state subcontracts and materials purchases] reduce the economic impact on the State, it is important to stress that, because of aerospace specialization within a highly diversified economy [the California economy], major contract awards to California firms will have a greater impact on the State economy than if such awards were made to firms in States having less reliance on the aerospace industry, or less diversified economies.[86]

This valid but carefully limited conclusion may be interpreted as meaning that a Space Shuttle prime contract awarded in California is likely to generate smaller employment and income effects in the other 49 States than it might if it were awarded in a State other than California. This comes about because the California economy, if it is more diversified and self-sufficient, has less need (and opportunity) to spread its subcontracts and materials purchases among suppliers in more distant markets in other States. If California as a consequence captures a greater than average share of the income and employment ("multiplier") effects, other States will gain accordingly less. In terms of both subcontractor and material-supplier activity, and in terms of the household expenditures of aerospace workers, a larger proportion of the direct economic effects, and the multiplied economic effects, of a prime contract let in California is likely to remain in California because more of the things required by the aerospace industry and by aerospace industry workers, are available within the State, than might be true in some other State.

Thus, one may conclude that studies and papers of the type just discussed, regardless of the particular State or region for which they might be done, do not reach the more fundamental issues discussed in the earlier portion of this chapter.

G. Effects in the Long Run and Short Run, Direct and Indirect

The discussion above includes the short-run national effects of a shift of expenditures to NASA R&D from all other Federal expenditures. It includes the long-run product supply effect of increased levels

[86] Rockwell International. Op. cit. p. 16.

of technology arising over many years following a sequence of expenditures on NASA R&D. The Chase report computes, in its section 4, the national macroeconomic impact of NASA R&D spending, when both the short-run demand effects, and the long-run supply effects, are taken into account. In the Chase study's section 4, both the short-run demand effects and the long-run supply effects of a $1,000,000,000 increase (not just a shift) in NASA R&D expenditures is analyzed. That is, instead of increasing the NASA budget by decreasing some other Federal budget items, as was done in section 2, in section 4 Chase computes the effects of increasing the entire Federal budget by $1,000,000,000 and allocating that $1,000,000,000 entirely to NASA and maintaining that annual funding level increment over a period of time. Chase concludes:

> that a $1 billion increase in NASA spending has approximately the same effect on aggregate demand and employment during the first two years as would a similar increase in other purchases of goods and services by the government, although the multiplier effects are larger than those which we obtain for tax cuts or increased transfer payments. However, the differences over a ten-year span are much different. While most types of Government spending add to aggregate demand without increasing aggregate supply, and hence eventually contribute to inflationary conditions, spending for R&D actually increases productivity and aggregate supply a sufficient amount so that the rate of inflation is lowered. While we have shown that this is also true to a smaller extent for other types of R&D spending, it is not true for those types of spending which do not increase productivity at all. Once again, these types of simulations can be calculated only with the macroeconomic approach.[36]

With respect to the long-run effects of increased productivity computed in this macroeconomic model along with the short-run demand effects of increased spending, Chase concludes as follows:

> [I]n the long run, [NASA R&D spending] expands the production possibility frontier of the economy by increasing the rate of technological progress. This improves labor productivity further, which results in lower unit labor costs and hence lower prices. A slower rate of inflation leads in turn to a more rapid rise in real disposable income, which permits consumers to purchase the additional goods and services which are being produced.
>
> Turning to the specific figures, a $1 billion sustained increase in NASA R&D spending will raise real GNP $23 billion by 1984, raise labor productivity by 2.0 percent and lower the level of the consumer price index by 2.0 percent. The unemployment rate will decline by 0.4 percent, and . . . 0.8 million new jobs will be created because of a more rapid expansion of the labor force. It should be noted that the demand component of increased spending results in only a $2 billion increase in real GNP by the tenth year, with the remaining $21 billion due to the permanent improvement in the level of technology.[37]

Both the Chase report and the GAO review of it indicate that further work is required to better define, and to make more certain, the magnitudes and the conclusiveness of the Chase results. The Midwest Research Institute study of aggregate productivity change is now eight years old; the Chase report is three years old.

The above summaries of the case study literature on specific technological effects indicate that productivity improvement analysis of specific industries is still in a very spotty and rudimentary state, even though they begin to substantiate the aggregate productivity results of Chase and MRI. The analysis of aggregate productivity is a very lively field of economic research, and activity in this field has

---

[36] Chase. Op. cit. pp. 97–98.
[37] Ibid. pp. 118–119.

999

been substantially stimulated in recent years by concerns over the productivity of energy. Without a continuing effort to extend and to update and to further synthesize the results so far obtained, the studies which form the background-in-literature for this present discussion rapidly may become obsolescent. It is possible however that the present review, comparison, and partial synthesis of the documents cited here, may suggest further extensions of the work now available.

H. Summary—What Do We Know Now About Economic Benefits From NASA R. & D.?

The studies reviewed here may be summarized in the following way. First, short-run demand effect analyses of the national type are relatively unimportant, and those of the regional type are probably misleading, for the purposes of national policymakers.

Second, NASA R&D probably has had positive national output productivity effects measurable in the aggregate, although differences and uncertainties remain over both methods and magnitudes. Because of the statistical problems which were raised in the GAO review, and which have not been answered in any subsequent statistical study, aggregate economic effects of the magnitude suggested by Chase cannot be said to have been conclusively demonstrated at the aggregate level.

Third, the case studies show very substantial technological improvements to a wide variety of industries arising from the primary technology applications of both communications and environmental satellite systems.

Fourth, the case studies of secondary effects suggest perhaps innumerable improvements in technology whose tangible and intangible benefits in the aggregate may be large, although their quantification as economic productivity gains is rudimentary at best.

Fifth, the Chase and Midwest Research Institute studies, together with the supplementary case study material provided by NOAA and Mathematica, provide the framework of an integrated demand and supply analysis. The aggregate economic analysis is supported and lent credibility by the case studies.

Sixth, however, much remains to be done to gain a fully conclusive picture, especially of the effects of *future* NASA R&D on the economy.

Seventh, although the General Accounting Office did not emphasize this, aggregate economic studies and industrial case studies can be continued both in parallel and in combination.

Dumping Space

[Tease]

SPACE SHUTTLE LAUNCH CONTROL *[voice-over]*: T minus 40 seconds. The development flight instrument recorders are on. T minus 35 seconds. We're just a few seconds away from switching control to the computer sequencer in the orbiter. T minus 31 seconds, and we have held.

ROBERT MacNEIL *[voice-over]*: Only 31 seconds before lift-off, the second launch of the space shuttle runs into a snag. Now NASA's biggest program, will the shuttle soon be NASA's only program?

[Titles]

MacNEIL: Good evening. Billions of dollars worth of the world's most advanced space technology was grounded today, apparently by a humble mechanical problem — a clogged oil filter. That caused computers to stop the scheduled launch of the space shuttle Columbia, in case the auxiliary power units that swivel the shuttle's main engines would not work. The launch will be delayed for about a week. Today's mishap comes as the shuttle is being made the target of increasing criticism in the scientific community. The criticism is not directed at the successful space shuttle itself, but at the fact that it's eating up more and more of NASA's budget just when that budget is being cut by the Reagan administration. Critics say the space agency's preoccupation with the shuttle will drastically change NASA's mission, killing off its pioneering role in space exploration and advanced scientific research. Tonight, what's left for NASA in space? Jim?

JIM LEHRER: Robin, for years the U.S. space program operated pretty much with an open checkbook. Unlimited funds were available to act on the unlimited imaginations of American space scientists. No more. A decline in the thrills and glory of early manned space flight had already brought some limits. Now the crunch over federal budgets and spending priorities has brought even more. NASA currently has a $6.1 billion budget, but there are reports the Reagan administration wants to trim $367 million off of it this year and $1 billion more from projected budgets in each of the next two years. More than half of its funds are dedicated to the space shuttle program, and its costs are supposed to go up in the next three years, thus making an even bigger bite of the total pie. That could result in the scrapping of other projects NASA has underway or under consideration — everything from Voyager II's look at the outer planets in a 1985 mission to Jupiter to further research into aeronautics. A hoped-for mission to photograph Halley's Comet when it comes into view in 1986 is already believed dead as is a mission to study the sun. Matching available money with all of these projects is the job of James Beggs, the head of NASA. He was appointed administrator in July, coming from the General Dynamics Corporation, where he was executive vice-president for aerospace. First, Mr. Beggs, the news on the space shuttle. Was what happened today a major complication, a major problem?

JAMES BEGGS: No. What we're up to is flying developmental flights, which we do with all new airplanes. This is an airplane, a flying machine. We ran into a developmental problem which I believe will be minor, but it is something that you have to worry about and so we felt we had to scrub the flight and go back and find out what was wrong. Basically, as you described it, we had a high pressure in an oil— a lubrication-oil system. Not serious, but enough so that we worried because the system that it was lubricating is one of the key systems in getting us back to earth.

LEHRER: What are the odds on it taking off next week?

Mr. BEGGS: Very good. We have a corrective action now underway. It will take about six days, and we believe we'll be ready to fly next Wednesday or maybe Thursday. If we run

into a little bit more difficulty in replacing pieces and parts, because it is in the aft-end of the vehicle where it's kind of tight. We've got the plumbing for all the main engines back there, so it's difficult to get in there and work. But if we can get in and do what we expect to do, we think about a week.

LEHRER: Did today's problems cast any doubts on the basic idea of the shuttle, the idea of a reusable spacecraft?

Mr. BEGGS: Not at all. As a matter of fact, I think what we ran into today is the kind of thing that really indicates the efficacy of the system. What we have is, to be sure, a very complex system, but a system which has been designed so that we can monitor every piece and part of it, so that we can work on every piece and part of it should we run into difficulty. The fact that we were able to halt the countdown and to pinpoint the trouble in a matter of about three-quarters of an hour indicates that we know the vehicle very well. The problem that we have is simply one of insuring that we can service the vehicle in a quick, ready, routine way and make it fly. We will be able to do that. We say we are going to go operational in about a year or a little less. We will be able to do this, we feel sure, because of the fact that we are, in the four developmental flights, uncovering the various service problems that we have.

LEHRER: Now, is the shuttle secure in terms of secure financial aid, no matter what happens to the NASA budget over the next three years?

Mr. BEGGS: Well, when you say "no matter what happens to the NASA budget," I can't judge that.

LEHRER: Right.

Mr. BEGGS: But, in terms of the commitment of this administration, yes, it's secure.

LEHRER: Is there a possibility— looking at it from the inside, where you have to look at it from, is it a possibility that the shuttle may, in fact, end up as the only major NASA program?

Mr. BEGGS: No, I don't believe that. We have had in the NASA program what we like to describe as a balanced program. The shuttle will reach its maximum expenditures in the next three years. We'll be spending something over $3 billion a year for the next three fiscal years, and so it is eating a substantial part of the budget, but we still believe we'll maintain the programs intact. The programs, of course, are, in addition to the manned program, the space sciences and planetary exploration, the applications program and the aeronautics program.

LEHRER: Well, let's go through some of those specifically. I mentioned them at the beginning. For instance, Voyager II and its 1986 and 1989 target to photograph some outer planets. Is that going to go ahead?

Mr. BEGGS: Of course. We're not going to fly two billion miles and not take pictures.

LEHRER: Okay. What about the Jupiter mission in 1985?

Mr. BEGGS: I think the Galileo-Jupiter mission remains intact in the budget.

LEHRER: What about the basic research in aeronautics that goes on in your facility in Cleveland?

Mr. BEGGS: Well, there are three centers that are associated with basic aeronautical research. In addition to Lewis in Cleveland, there are Ames out in the South Bay Area in San Francisco and the Langley Center just south of here in Langley, Virginia. Those centers have, since 1915, conducted an extensive program of basic research and they remain intact. The real question there that has been examined and is still being examined is, how much prototype work or actual flying of hardware that we do. But the major facilities, and NASA is the repository of the major aeronautical facilities of the country, which exist in those three centers and which serve the industry and the university community in aeronautics, remain

very well alive and doing very good work.

LEHRER: Well, Mr. Beggs, it sounds to me like you're saying that you're going to be able to continue to do everything with less money. Is that what you mean?

Mr. BEGGS: No, I'm not saying that. NASA has, since about 1972, had a reduction in buying power. If you go back to 1972, the NASA budget was somewhere between $3.3 and $3.4 billion, and it has been reduced almost every year since that time. If we had the same buying power that we had in '72, we would have over $7 billion now, so we're operating with less money. We've reduced our manpower from what was then about 33,000 or 34,000 civil service people to about 22,000. So we've had a substantial cutback. We believe that we still have a very viable program at that level. Further reductions from that would be— would be problems to us, and it would mean that we would have to examine the various program areas and decide which we might have to give up. But right now, with the budget we have in '82, and with that we have in prospect in '83, we have adequate funds to continue that balanced program that I described.

LEHRER: Thank you. Robin?

MacNEIL: Last month, two scientists appealed directly to the White House to save key parts particularly of NASA's planetary exploration program. One of them was Carl Sagan, author, lecturer, professor of astronomy and space at Cornell University, and host of the PBS-TV series, "Cosmos." Mr. Sagan, first of all, are you reassured by what the administrator, Mr. Beggs, has just said?

CARL SAGAN: At least a little bit. I mean, it would have been monstrous to turn off the Voyager cameras when all the money had been spent in flying for the first time past Uranus and Neptune, and Galileo is the only approved mission of this decade to explore the other planets. There were dozens in the decades of the '60s and the '70s. So I'm slightly reassured by this, but it's still, if nothing more than this is done in space science, it's an exceptionally spare and ugly, dangerously small budget.

MacNEIL: In what way "dangerous?"

Dr. SAGAN: Well, in several respects. One is that the teams of engineers and scientists who have created this remarkable American accomplishment of exploring every planet from Mercury to Saturn, every little light in the sky that moved, known to our ancients. For the first time in human history, they've been explored close up and with some scientific rigor. For us to back off from that historically significant program seems to me exceptionally short-sighted.

MacNEIL: But Mr. Beggs said that those programs of the space sciences and planetary exploration will remain intact.

Dr. SAGAN: Well, it depends on which programs we're talking about. As I said, in the '60s and '70s there were dozens in each decade. In this decade there is one. I'm delighted that that one is not being canceled.

MacNEIL: That's the Voyager?

Dr. SAGAN: No. Voyager—

MacNEIL: The new Galileo one to Jupiter.

Dr. SAGAN: That's Galileo, yes. You see, we have the sense, from the enormous success and the great popular attention devoted to Viking at Mars and Voyager to Jupiter and Saturn, that things are going splendidly well, but that's the— we are the beneficiaries of decisions made in the '60s and '70s, because the lead times are so long for these missions. There are no new starts in this decade, with the single exception of Galileo, in planetary exploration, and that worries me greatly.

MacNEIL: Well, is what worries you the fact that no yet newer ones are being planned, or

that things already planned are being canceled, and can you name some specific—

Dr. SAGAN: Well, there are different levels of planning, but for example, Halley's Comet is an astronomical object fabled in song and story. It will approach the earth in 1986. We have the capability for the best exploratory program of Halley's Comet of any nation on the planet. The United States will not — unless a decision to the contrary is made essentially a week from Tuesday — explore Halley's Comet, while there will be a joint Soviet-French set of spacecraft to examine it. There will be a mission from the European space agency, and Japan will launch its first planetary mission.

MacNEIL: Well, if all those countries are doing it, won't international science, and therefore American scientists, benefit from the knowledge they reap?

Dr. SAGAN: No question about it. And my sense that these scientific exploratory programs should be done in the name of all the people of the planet earth is very strong. But the United States has some remarkably potent experience and capabilities, and this is an exercise which harms no one, which is widely acknowledged all over the world as a benevolent aspect of American technology, even in nations which disagree with us on virtually everything else. And what's more, we have some particular capabilities because of the enormous experience we have that no other nation has to perform such exploratory ventures. These are explorations which pump high technology, which have enormous public appeal— for example, there's an organization called The Planetary Society which has 100,000 members devoted only to interest in planetary exploration. And it's a venture of enormous historical significance. I think that 1,000 years from now the particular political crises that we're so focused on will be as obscure as the causes of the War of the Austrian Succession are to us today. But what will be remembered about this time — provided we don't destroy ourselves — is that this is the moment when we first set sail for the planets.

MacNEIL: A large part of the NASA budget is going into the space shuttle, as we said, and as the administrator has confirmed — $3 billion or so a year. What is wrong with putting such a large part, in your view, into the space shuttle?

Dr. SAGAN: Well, for one thing, the space shuttle is, to a significant degree, pumped by military requirements. And whether that's good or bad is a separate issue, but it seems to me this is a case of borrowing or stealing from the poor — namely NASA — to benefit the rich, namely the Department of Defense. The NASA budget is a very tiny fraction of the Department of Defense budget and yet it is NASA which has to develop the launch system for Department of Defense reconnaissance and other satellites. And so I think that's one thing that's wrong. This country has very few places where we are acknowledged world leaders, especially in activities that everybody says benefits the entire population of the planet. To take away from that very small pot of money and give it to the Department of Defense, which has such an enormous budget — over $1 trillion for the next few years — seems to me a serious mistake.

MacNEIL: Well, thank you. Jim?

LEHRER: President Reagan has given his White House Office of Science and Technology the major assignment of reviewing NASA and where it should go from here. The head of that review group is Mr. Reagan's science advisor, George Keyworth. He is a nuclear physicist who headed the Los Alamos National Laboratory in New Mexico before joining the administration. Mr. Keyworth, Dr. Sagan says that the spare space program that the United States is now working on is dangerous. Do you disagree?

GEORGE KEYWORTH: The spare space program?

LEHRER: He called it "the spare space program," that's so spare.

Dr. KEYWORTH: I beg to differ. And let me back up a little bit in perspective. Our administration is committed, I think, to maintain the leadership that the United States has today across the spectrum of science and technology, including space. Today we have a new

capability inherent in the shuttle. It's very different than what we've had for the last 10 or 15 years. What we are trying to do is to utilize the shuttle to develop some new areas of space science. Remember, the solar system, as interesting as its origins and evolution has been and will continue to be, is only a very small part of the universe. There's an enormous new field of space science that can be addressed with the shuttle.

LEHRER: Yes, but Dr. Sagan says that it's primarily the military priorities that have made the shuttle such a big priority and that NASA's civilian responsibility is being pushed aside as a result.

Dr. KEYWORTH: I think that we are still continuing to focus primary emphasis on the entire space program, upon the science and the civilian applications, and I think that's probably what continues to occupy Jim Beggs as primary considerations, for example.

LEHRER: What about his concern about no new projects, that back in the '60s and '70s there were 10, 12, whatever, new space exploration projects? Now there's only one new one on the boards, and that's Jupiter in 1985.

Dr. KEYWORTH: Well, I'll use his point to emphasize what I was trying to say initially about a new space program. It's true that Galileo is the only new start in planetary science, but let's look at the space telescope, which will be coming— will be launched in 1984. I think this is perhaps the single most exciting bit of space science that has ever been undertaken by us or any other nation.

LEHRER: And that's going to stay, right, as you understand it?

Dr. KEYWORTH: Very much so.

LEHRER: I see. Now, what is the scope of the review you're doing of NASA and the space program for the President? Is it a long-range, "where should NASA go," or is it a short-range, "how are we going to live with the budget cuts?"

Dr. KEYWORTH: Oh, it's very long range. First of all, it really was begun and initiated by the President out of context of the budgetary considerations. The objective is really to look at the next 10, 15, 20 years of our space program based upon this new capability inherent in the shuttle. What are we going to do? What is our balance going to be between space science, between applications, between planetary science and astrophysics, and what are the directions that we should begin now and emphasize in the future?

LEHRER: And when is your review supposed to be finished?

Dr. KEYWORTH: Oh, no firm deadlines, but I think we'll probably be finished formally within a matter of months.

LEHRER: And is the President himself going to make the final decision on this when he goes to Brother Beggs and says, "Look, here's what I think NASA ought to do?" Or is it going to be a budget thing made by the OMB?

Dr. KEYWORTH: No, no. It'll be a policy decision. The President asked me to initiate this study, working with the other agencies. I will report to him with our joint perspective and perhaps my recommendations, but the decision, I assure you, will be the President's.

LEHRER: Are you as concerned as Dr. Sagan is over the decision not to go ahead with the Halley's Comet project?

Dr. KEYWORTH: No, I wish we could do the Halley's mission. I wish we could do a number of other missions, but I think we're going through a very healthy exercise right now in trying to identify the richest, the healthiest overall space program. And I think we have a — just as Jim Beggs said — a very healthy program laid out that we can afford to support.

LEHRER: And you're not concerned also, as he is, about dismantling the expert teams that are now in place at NASA or in conjunction with NASA?

Dr. KEYWORTH: Oh, no. This is a period of transition. I think we'll be putting emphases in some new areas and deemphases in some others. But, no, I don't see any wholesale dismantling or anything resembling it.

LEHRER: But right now it is, as you say, it's all based on the shuttle — the future, right? As we sit here now?

Dr. KEYWORTH: Oh, most heavily, yes.

LEHRER: Thank you. Robin?

MacNEIL: Mr. Beggs, your turn to be asked if you are reassured by what you just heard. Are you satisfied— you said a moment ago that if there were further reductions there would be problems. Has the White House reassured you that there are not going to be further big reductions?

Mr. BEGGS: Well, let me— let me direct myself to the basic question which Carl Sagan was talking to. And I'd like to make maybe two or three points. First of all, it is true that we had an extraordinary decade in the '70s in planetary exploration. It was a culmination of a lot of things that we had started about the time that we were reaching the peak of our Apollo program — the flights to the moon. And it resulted in many, many very important and very exciting projects, the last of which are the Voyagers. They're very important, very exciting, and very productive. They have asked a lot of questions and have addressed the scientific community to further exploration. That further exploration, which undoubtedly will be conducted over the next couple decades, will be the subject of intense study by NASA and by the scientific community. The amount of money that we devoted to those activities, as a percentage of the NASA budget, has remained about constant for the entire life of the agency. NASA became an independent agency in 1958. And for the little over 20 years that we've been in existence, the percentage of money devoted to space science and planetary exploration has remained about constant as a percentage of our budget. Now, we have in being the Galileo mission going back to Jupiter to probe the atmosphere of Jupiter, a very important scientific mission, which will answer a lot of questions which have been asked by the Voyager series and by the Pioneer series. We also have in existence the large space telescope which will enable us to peer out into the cosmos that Dr. Sagan has promoted so effectively and so well. And we have planning for another mission to Venus, which will come on in the latter part of the '80s, and so we still have what I consider to be a healthy planetary exploration of man's role in the earth and the cosmos. It is not as big as everyone would like, but then again, there is not a single program that is being conducted by the federal government that is as large as its proponents would like.

MacNEIL: Let me put that back to Dr. Sagan. You've heard the administrator say that the percentage of NASA's budget devoted to space sciences and planetary exploration remains the same as it has been.

Dr. SAGAN: Well, yeah, but the absolute value has been declining. The number of missions — lunar and planetary missions — in the decade of the 1960s was 24; in the decade of the 1970s, it was 14, and in the decade of 1980s is one or two. Now, that is a substantial decline. Dr. Keyworth said that we shouldn't forget about the space telescope as an historic— and that it would open up remarkable new windows to the universe, and I am a very major enthusiast of that space telescope. But the space telescope is not a new start of the Reagan administration or the 1980s. We are again the beneficiary of a new start made in the 1970s. The question is, because the lead times are so long, because scientists cannot forever wait, hoping that there'll be some new mission — they have to do something to support their families — the question is, what new, major starts in space science — apart from planetary exploration — are going to be done by the Reagan administration?

MacNEIL: Let's ask Mr. Keyworth. Dr. Keyworth, what new starts are going to be done?

Dr. KEYWORTH: Well, another one that I feel very enthusiastic about is what we call the

gamma-ray observatory. I think it offers, in addition to the optical, that is, visible-light capabilities of the space telescope, it offers us an enormous opportunity to understand and explore rapidly pulsing suns in the distant regions of our universe.

MacNEIL: Is that a new start by your definition?

Dr. SAGAN: Oh, if this represents a commitment to the gamma-ray observatory, I am, at least as far as this goes, delighted. Is that what's being said?

MacNEIL: Is that what is being said, Dr. Keyworth?

Dr. KEYWORTH: We're talking about a launch that would occur later in the decade, but, yes, I think we're all very committed to trying to maintain stimulus and development of the gamma-ray observatory, yes.

MacNEIL: Let me come back with Mr. Beggs to another question that Dr. Sagan raised. Are you happy, Mr. Beggs, about so much of your budget, which is a small budget by comparison with the Pentagon's, going to support and enhance a program of which the Pentagon will be a major beneficiary?

Mr. BEGGS: Well, I've got a quarrel with the basic premise there. The military is indeed a beneficiary of the shuttle, but the shuttle stands on three legs, only one of which is military; the other is commercial, and applications work; and the third is the space science and planetary exploration that we are talking— we have just finished talking about. The military is by far the minority of the number of missions in the mission model that we will be flying the shuttle. The shuttle is a means to an end. It's a transportation system. It will provide a routine, economical means of going into space and of exploring the various options that we have in the future to do the great things that we must do. We have had an extraordinary history in the last 20 years which, as I said earlier, points out a number of directions that we'd like to go. We felt back in the early '70s that we needed a more economical transportation system to exploit the next couple decades. That's the shuttle. Now, we are coming to the point where we are about to make that operational and we must, we have to, we have no choice here— we must finish that program and we must finish it so that it gives the promise that it offered in the beginning.

MacNEIL: We have to—

Mr. BEGGS: When we do— when we do, we will have a system that is not only useful for the military, but is extraordinarily useful for the commercial applications and science programs that we are going to have in the next couple decades.

MacNEIL: That's the end of our time, Mr. Beggs. Thank you very much for joining us. Thank you, Dr. Keyworth, in Washington, and Dr. Sagan here. Good night, Jim.

LEHRER: Good night, Robin.

MacNEIL: That's all for tonight. We will be back tomorrow night. I'm Robert MacNeil. Good night.

THE ECONOMIC BENEFITS OF OPERATIONAL ENVIRONMENTAL SATELLITES

by

W. John Hussey*

Abstract

Satellite observations of the atmosphere on a global scale began 23 years ago. In the intervening period, satellite sensors and operational techniques for the use of the data has evolved to a high degree of proficiency. This paper identifies and attempts to quantify, to the extent possible, many of the current benefits and uses being derived from the United States' Operational Environmental Satellite System.

The initial paper on this subject was published by W. John Hussey and E. L. Heacock in April 1978 and presented at the Fourth Annual Convention of the Eastern Economic Association in Washington, D.C. Subsequently, there has been considerable interest in the evolving benefits of environmental satellites and the primary benefits discussed in the 1978 paper have been updated and included in this paper. In addition, many other unique uses of environmental satellite data are discussed in this paper.

The benefits discussed herein are evidence that the operational environmental satellite has earned its place as an irreplaceable weather and ocean observing tool. These satellites are making major contributions towards the saving of lives and property from natural disasters and improving the efficiency of many sectors of our national economy.

TABLE OF CONTENTS

I. Overview of the Operational Environmental Satellite Program

1. Operational Environmental Satellite Program Mission Objectives
2. Geostationary Satellite System
3. Polar Orbiting Satellite System

II. Activities Benefiting from Operational Environmental Satellite Programs

1. Ocean Current Navigation for Fuel Savings
2. Commercial Fishing Industry
3. Agricultural Industry
4. Search and Rescue Operations
5. Ice Monitoring
6. Snow Cover Mapping
7. Natural Disaster Warning
8. Large Scale Weather Forecasting
9. Miscellaneous Activities

A. Airline Fuel Savings
B. Game Bird Management
C. Dust Storm Monitoring
D. Locust Plague Control
E. Volcano Monitoring
F. Metropolitan Planning
G. Hydroelectric Power Production
H. Forest Fire Prevention and Detection
I. Bowhead Whale Monitoring
J. Water Quality Monitoring
K. Recreational Boating

III. Summary

38-036 O - 84 - 29

1. Operational Environmental Satellite Program Mission Objectives

The Nation's operational environmental satellites are operated by the National Oceanic and Atmospheric Administration's (NOAA) National Environmental, Satellite, Data, and Information Service (NESDIS). The mission objectives of this operational satellite program include:

I. Monitoring the atmosphere regularly and reliably on a global basis, day and night, with direct readout to local ground stations around the globe within radio range of the satellites.

II. Sounding the atmosphere regularly on a global basis and providing quantitative data for numerical weather prediction services.

III. Continuous monitoring of environmental features in the western hemisphere, and the collection and relay of environmental data from remote platforms such as buoys, ships, automatic stations, aircraft, and balloons.

IV. Applying environmental satellite data for the purpose of improving environmental services.

2. Geostationary Satellite System

NOAA's Geostationary Operational Environmental Satellite (GOES) system includes two satellites, the ground data acquisition station, and a centralized data distribution system. The first satellite in this system, NASA's Synchronous Meteorological Satellite (SMS-1), a prototype for GOES, was launched May 17, 1974. The latest in the SMS/GOES series, GOES-5, is the seventh operational geostationary spacecraft to be operated by NESDIS. The next GOES satellite, GOES-F, is scheduled to be launched from Cape Canaveral in April 1983. Two additional GOES spacecraft are being built by the Hughes Aircraft Company. These have been designated GOES G and H and are scheduled to be launched in 1986. The next generation geostationary environmental spacecraft called GOES NEXT is in the preliminary planning stages. It is scheduled to be available for launch in mid-1989 to ensure continuity of geostationary coverage. The GOES NEXT series is planned to cover a 12 year period beginning in 1989.

The operational system consists of two satellites; GOES West located over the equator at 135° West longitude and GOES East located at 75° West longitude. GOES West observes North America and the Pacific Ocean to west of Hawaii and GOES East observes North and South America and most of the Atlantic Ocean. These geostationary spacecraft are in circular orbits at an altitude of approximately 35,800 km. (22,240 miles).

The primary instrument carried by GOES satellites is called the Visible Infrared Spin-Scan Radiometer (VISSR) Atmospheric Sounder (VAS). This instrument, first carried into space on GOES-4, provides the traditional visual and infrared imagery of cloud cover and the earth's surface. In addition, VAS provides measurement of infrared radiation which can be used, with known atmospheric properties, to calculate atmospheric temperature profiles over selected geographic areas. It can also produce images in multiple IR spectral bands instead of the single band produced by the VISSR. This new capability is called multispectral imaging and has proven very useful in depicting the amount, distribution and movement of water vapor at various levels.

The VAS provides a full disc view of the earth every 30 minutes. More frequent images can be obtained at the sacrifice of spatial coverage. The visible channel provides high resolution (about 1 km) daytime images. The infrared channel provides lower resolution (about 8 km) day and night images. The GOES images are processed through the NESDIS Central Data Distribution Facility, either as a full disc image or a sector of this full disc image. These products are routed to Satellite Field Services Stations (SFSS) for analysis with further routing to National Weather Service Forecast Offices and other users.

The SFSS's are located at Washington, D.C.; Miami, Florida; Kansas City, Missouri; San Francisco, California; Honolulu, Hawaii; Anchorage, Alaska and Slidell, Louisiana. Each SFSS provides regional analysis, interpretation, and distribution of the VAS images to meet a wide variety of environmental needs. A most important service is the near-continuous viewing of the development and movement of severe weather systems such as hurricanes and thunderstorms. An extension of the GOES image distribution service is the "GOES-TAP" system. Established by NESDIS in 1975, "GOES-TAP" allows Federal, state, and local agencies, television stations, universities, and private industry to receive an inventory of GOES satellite images directly from the nearest SFSS. In addition, the GOES satellites broadcast environmental products to remote locations using the Weather Facsimile (WEFAX) System.

The GOES satellites also carry a Data Collection System (DCS) which collects and relays environmental data obtained by remotely located sensing platforms such as river and rain gauges, seismometers, tide gauges, buoys, ships, aircraft, and automatic weather stations. Each operational GOES spacecraft can accommodate data from more than 10,000 platforms each six hours. Data are normally transmitted in a self-timed mode or upon interrogation by the satellite. Data may also be transmitted under emergency conditions in which the platform transmitter is triggered whenever an observed parameter exceeds a predetermined threshold value. About 3,600 + platforms now provide environmental data to users in the United

States and Canada. The geostationary satellite DCS provides a near-instantaneous source of information for many applications such as river level and flood monitoring and forest-fire index measurements.

Also included in the GOES instrument complement is a Space Environment Monitor (SEM) which provides measurements of solar activity for detecting solar flares, the intensity of the solar wind, and the strength and direction of the earth's magnetic field. The SEM data which is included in the satellite telemetry data stream is received at the NOAA Space Environment Services Center (SESC) in Boulder, Colorado. These data are separated out of the telemetry stream and processed in the SESC data base. When significant solar events are detected, the SESC issues warnings to a number of users throughout the United States. Routine forecasts of solar activity and its implications such as interference with high frequency radio transmissions, are also distributed by SESC.

3. Polar Orbiting Satellite System

NOAA's operational polar orbiting satellite system is called the TIROS-N/NOAA series and consists of two satellites and the ground data acquisition and processing systems. The first spacecraft in this series called TIROS-N was launched on October 13, 1978. There are two polar orbiting satellites currently in operation providing global coverage at different times of the day. NOAA-6 is in a morning orbit (0734 local equator-crossing time descending) and NOAA-7 is in an afternoon orbit (1453 local equator-crossing time ascending). These satellites are in sun-synchronous orbits at altitudes of 808 km and 847 km, respectively. The orbital period is 102 min. which equates to 14.2 orbits per day.

The next TIROS-N/NOAA satellite, NOAA-E, is scheduled to be launched from Vandenberg AFB, California in March 1983. Three additional NOAA spacecraft are being built by RCA Astro-Electronics These have been designated NOAA F, G, and D and are scheduled to be launched in 1984, 1985, and 1986/87 respectively. Three other polar orbiting spacecraft, NOAA H, I, and J are in the planning stages.

The TIROS-N/NOAA series utilizes four primary instrument subsystems. These are:

1. Advanced Very High Resolution Radiometer (AVHRR)
2. TIROS Operational Vertical Sounder (TOVS)
3. Data Collection System (DCS)
4. Space Environment Monitor (SEM)

The AVHRR provides visible and IR image data for real-time transmission to direct readout users and for storage on the spacraft tape recorders for later playback. The AVHRR consists of five channels which provide data on daytime cloud cover, snow and

ice coverage, nighttime cloud cover and sea surface temperatures. The direct readout High Resolution Picture Transmission (HRPT) has a resolution of 1 km in all spectral channels. The Automatic Picture Transmission (APT) provides an undistorted resolution of 4 km. There are over 800 APT receiving stations and 76 HRPT receiving stations located in approximately 123 countries throughout the world.

Also available is on-board recording of the 4 km resolution data which provides Global Area Coverage (GAC). Selected on-board recording of the 1 km resolution data is available as Local Area Coverage (LAC). The recorded data is played back to the NOAA Command and Data Acquisition (CDA) stations located near Fairbanks, Alaska and Wallops, Virginia. The data are subsequently transmitted via a domestic communications satellite to the NOAA central data processing facility in Suitland, Maryland.

The TIROS Operational Vertical Sounder (TOVS) includes three complementary sounding instruments. These are:

1. High Resolution Infrared Radiation Sounder (HIRS/2)
2. Stratospheric Sounding Unit (SSU)
3. Microwave Sounding Unit (MSU)

The HIRS/2 provides data which permits calculation of temperature profiles from the surface to 0.1 mb ($\sim$215,000 ft.), the water vapor content of the atmosphere and the total ozone content. Data from the TOVS instruments are also broadcast via the direct readout transmission links. The SSU instrument is provided by the United Kingdom.

The Data Collection System (DCS) is provided by France. It is called the ARGOS Data Collection and Platform Location System. The ARGOS system provides a means to locate and collect data from moving platforms. The platform data are stored and relayed to the Suitland center where it is separated and relayed to the CNES Toulouse Space Center in France. There, the data are processed, earth located and relayed to the ultimate user.

The TIROS Space Environment Monitor (SEM) includes three detectors which measure solar proton flux, alpha particle and electron flux density, energy spectrum and total particulate energy distribution at spacecraft altitude. The data from the SEM are stripped out of the spacecraft telemetry stream and transmitted to NOAA's Space Environment Services Center (SESC) in Boulder, Colorado. These data are used to monitor the state of solar activity which has a significant effect on terrestrial communications, electrical power distribution, etc.

II. Activities Benefiting From Operational Environmental Satellite Programs

Following is a synopsis of several specific examples of the economic benefits and also intangible benefits, such as lives saved, which are derived directly from operational environmental satellite data or from a combination of satellite and "conventional" weather data. It should be recognized that many of these benefits are possible because of the operational nature of the environmental satellites. In other words, users can depend on the availability of these data today, tomorrow, and in future years. Therefore, users can afford to invest in special data handling and processing equipment, software, and techniques with confidence that these satellites will be available to provide the data they require year after year.

1. Ocean Current Navigation for Fuel Savings

Use of the swift Gulf Stream currents to increase northbound steaming speed is an old idea, but utilizing that idea has not been easy. The swiftness and great variability of the Gulf Stream position creates many uncertainties and hazards to navigation. Much of the uncertainty is created by eddies and meandering of the Stream. Meanders can be 250 miles across and the stream axis can move as much as 60 miles in a week.

A 1975 Gulf Stream Navigation Experiment conducted jointly by the EXXON Company and the National Oceanic and Atmospheric Administration (NOAA) showed that significant fuel savings can be realized by using timely satellite analyses of the Gulf Stream position for oil tankers navigating along the eastern seaboard. An improved NOAA satellite capability, operationally available with the launch of NOAA-2 in 1972, was infrared measurement of sea-surface temperatures. Enhanced infrared images representing sea-surface temperature differences clearly delineated the warm Gulf Stream in contrast to the colder shelf water. The joint EXXON/NOAA experiment was conducted to test whether using satellite-derived Gulf Stream analyses could improve navigation enough to realize significant fuel savings. NOAA analyzed the satellite infrared images of the Gulf Stream's western boundary called the "Western Wall"; and estimated the axis of maximum current velocities relative to the Western Wall. EXXON arranged for radio broadcast of the information to their tankers at sea.

Eleven EXXON tankers, steaming from the Gulf of Mexico to east coast ports and returning, participated in the experiment. Five were instructed to follow the usual navigational practices, which used or avoided the Gulf Stream in a relatively random manner. The other six were to use the NOAA satellite analyses for their navigation. In other words, the tankers were to transit within the Gulf Stream northward and avoid the Gulf Stream on their southbound journey.

The seven month study showed a very definite fuel savings for the six vessels using the NOAA data. EXXON, assuming a total of 15 tankers navigating by satellite data, projected savings amounting to 31,500 barrels of fuel oil. Using a 1975 cost of $11.50 per barrel, the EXXON study reported a potential annual fuel savings of around $360,000 for their company alone. Assuming a 1982 cost of $30.00 for a barrel of fuel oil, the estimated annual savings would be around $945,000 for 15 tankers navigating the Gulf Stream effectively. Use of satellite derived Gulf Stream position data is now standard navigating procedure for all ships of the EXXON fleet. Applications of this information by all coastal traffic of the U.S. merchant marine is possible and could result in significant savings of U.S. fuel resources. The analyses are made available by automatic telecopier and radio broadcasts.

A similar product is available for Gulf of Mexico navigation. A clockwise flow of warm water from the Yucatan Straits, around the Gulf, and out through the Florida Straits is quite strong. The coastward edge of the warm water in this "Loop Current" is marked by a thermal gradient which is great enough in the cold winter months to be discerned in the satellite infrared imagery. The NOAA Miami Satellite Field Services Station produces a Loop Current Bulletin (November to May) which aids ships in the Gulf of Mexico to use the Loop Current for assistance in a manner similar to the use of the Gulf Stream described above. These analyses are also available by automatic telecopier.

The Crowley Towing and Transportation Company of Jacksonville, Florida operates 60 vessels in the West Indies and Gulf of Mexico and has stated that accurate knowledge of the Gulf Stream and Loop Currents is vital to their operations. An on-going fuel conservation program has been enhanced by this satellite information with fuel savings of 20-40% obtainable when their 9000 Hp tugs are able to reduce engine rpm by 18%, with only small reduction in speed. They are experiencing up to $2000 per steaming day savings on their line haul tugs. Other Crowley barge sailings returning north from Cuba via the Santaren Channel utilizing the Gulf Stream to the utmost, are improving their average speed from 9.5 to 12.0 knots which on a bi-weekly basis saves 8 hours per voyage. This totals 192 hours per year or 8 days per year at an average equipment operating cost of $15,000 per day.

2. Commercial Fishing Industry

The NOAA Satellite Field Services Station at San Francisco has produced charts derived primarily from the polar orbiting satellites' Very High Resolution Radiometer (VHRR) infrared imagery depicting the location of thermal boundaries or "fronts" as part of an operational sea surface temperature analysis. It has been well documented by marine biologists and fishermen that certain species of fish are temperature-sensitive. Albacore (blue fin tuna) and coho (silver) salmon, the principal commercial fish found along the west coast, tend to congregate in nutrient rich waters in the vicinity of thermal fronts. Albacore are found in temperatures ranging from 16°C - 20°C, while salmon prefer temperatures of 11°C - 13°C.

Since 1975, the National Environmental Satellite, Data, and Information Service (NESDIS) has been issuing Sea Surface Temperature (SST) Frontal Charts from the SFSS in San Francisco to aid fishermen in locating these "productive" areas. In 1981 the SFSS began producing a sea-surface thermal analysis incorporating satellite-observed thermal features. Geographically, the area originally covered by the charts extended from 34°N to 49°N and from the coast to 128°W. Since 1981, only one area has been charted and that extends from 28°N to 40°N and west to 136°W. It is known that the food chain is often concentrated along these fronts, usually as a result of the seasonal upwelling process that takes place along the west coast of the United States. Charts produced when skies are cloud-free, have greatly assisted commercial albacore and salmon fishermen in locating fish productive areas. Results were so encouraging that the program was expanded to cover most of the West Coast.

The IR images, received up to four times daily, are enhanced using computerized tables to assist in the identification of the thermal gradients. The changes in temperature are represented by changes in the tones of gray in the enhanced satellite image. The frontal postions are analyzed directly on the image and then transferred to a marine navigational base chart. These analyses are produced twice a week. The latest chart is transmitted twice daily by radio facsimile from Point Reyes, California, and by automatic telephone telecopier.

Satellite images are also transmitted twice per day to the Seattle Ocean Services Unit of the National Weather Service. This unit produces a satellite derived thermal boundary and sea surface temperature analysis extending from 40°N to 52°N which is distributed to Pacific Northwest fishermen via a telecopier system, mailing list, and direct telephone briefings.

An example of how the fishing community has received this product is indicated in a quote from the Summary of Pacific Input to the Eastland Fisheries Survey prepared by the Pacific Marine Fisheries Commission as their input to the nationwide Eastland Fisheries Survey, a report to Congress dated May 1977. This report states (underscore added):

> "Commercial salmon and albacore trollers emphasized that the federal government should not be involved in developing new equipment and methods for locating fish with one exception. They support the use of satellite pictures which display temperature gradients and indicate that the federal government should continue to use existing satellites to provide this information. Present methods for developing and providing advisories are adequate and existing advisories for the albacore fleet should continue. More emphasis should be placed on provision of practical information such as water temperature, weather, and currents...."

The commercial fishermen are beset with a number of problems which include changing and more stringent regulations and increasing fuel costs. By delineating those areas which are often fish-productive through the use of infrared satellite imagery, a fisheries management tool is available whereby commercial fishing can become more efficient and thus more cost effective. Fishermen can disperse over larger areas when productive frontal locations are known thus helping to avoid overfishing small areas.

During the initial experiment in 1975, it was estimated that approximately 200 salmon and albacore fishing vessels were able to save $580,000 in fuel costs as a result of using satellite data. The albacore fishery has the most direct benefit from the satellite data since they are very temperature oriented. The salmon industry benefits to a lesser extent. Mr. Fred Jurick formerly of the NOAA Sea Grant Program, Marine Advisory-Extension Service at Humbolt State University in Arcata, California was a pioneer in the use of satellite data to directly support fishermen. Mr. Jurick correlated catches of albacore and salmon ranging from $2,000 to $14,000 directly to the use of the satellite derived thermal front charts. One commercial salmon troller stated that he caught an extra $10,000 to $12,000 of fish (which was about one-third of his total seasonal catch) as a direct result of using the thermal front charts.

If one uses the figures provided by the National Marine Fisheries Service, and places a modest savings of 10% on the fuel bill for each of 1000 fishing vessels in operation off the West Coast, the annual fuel savings for the fleet is $440,000. If one then adds a "catch advantage" of $2000 worth of fish per vessel (approximately 2 ton of albacore) due to time saved and improved location of the fish, one has an annual benefit of $2,440,000 to the fishing industry on the West Coast. This figure is conservative since there are more than 1000 vessels fishing off the West Coast.

In Alaska, the weekly Sea Surface Temperature (SST) charts are distributed by the Anchorage Satellite Field Services Station to approximately 200 users of which 65% are commercial fishermen/processors, 15% are Federal and state agencies, 10% are oil industry and 10% are research organizations. These SST charts provide guidance to commercial fishermen and fisheries researchers concerning the expected arrival of commercial species to Alaskan waters: herring (SST 4°C); red salmon (SST 7°C) in Bristol Bay; silver salmon (SST 11-13°C) in Southeast Alaska; and pink salmon (SST 11°C) near Kodiak Island thus saving travel time, labor and fuel costs. This information is being used for local fish inventory and migration studies and fish harvest forecasting.

NOAA sea surface temperature and ice condition charts derived from polar-orbiting satellite data have saved an Alaskan herring processing plant an estimated $7000-$8000 per day in wages and fuel costs. Using these data, the company determines where it should send its floating processing plant for herring runs. Multiplied by 8-10 processors over a month's time, the savings are subtantial. Commercial fishing for silver salmon around southeast Alaska has also been enhanced by the location of the 11°C isotherm. Catch increased from 50 to 200 salmon a day; again trolling costs (fuel, equipment and time) are significantly reduced.

Other Alaskan users are the king crab fishermen in the southern Bering Sea and Bristol Bay. In 1980, the king crab fishermen lost more than $3 million in crab pots due to untimely ice formation. These fishermen now use the satellite derived ice charts to determine when to retrieve their pots prior to ice formation.

On the East Coast, the swordfish is one of the few temperature-sensitive fish in the Atlantic. Swordfish prefer areas with temperatures ranging from 13° to 25°C. The East Coast fishermen supplement satellite derived data with information on water depth and the migration routes of the swordfish. The president of the Swordfishermens' Association stated: "Receiving these charts has resulted in a tremendous savings of time. We used to spend up to five days looking for the fish, and now we can go right to the place where the fish are located. When you figure that most boats

will use from 20 to 50 gallons of fuel an hour, you can recognize the savings involved. There are about 500 vessels in the swordfish fishing fleet."

For completeness and comparative purposes, the dollar value of all pelagic and benthic fish species caught in the major fishing regions within U.S. waters in 1981 are shown in the following table. Note that 62% of the dollar value of these species were caught in Alaskan and Californian waters. It is interesting to note that satellite data support to the fishing industry is utilized to a greater extent in Alaska and California than in any other major U.S. fishing area.

Value of All Pelagic and Benthic Fish Species Caught in 1981

	Dollar Value	Percent
Alaska	$ 639,797,000	43
California	275,196,000	19
Maine	196,854,000	13
Louisiana	193,549,000	13
Texas	174,787,000	12
	$1,480,183,000	100

Internationally, NOAA satellite-derived sea surface temperature data are used to aid commercial tuna fishing by the Portugese near the Azores and by a consortium of New Zealand companies and the Star-Kist Tuna Company fishing around northern New Zealand.

3. Agriculture Industry

A. General

A study published in 1973 by the Space Science and Engineering Center of the University of Wisconsin showed that improved weather information and forecasting could provide large economic benefits to the agriculture industry. The purpose of the study was to determine the value of improved weather information and weather forecasting to farmers and agricultural processing industries in the United States. The study, funded by NASA, was undertaken to identify the production and processing operations that could be improved with accurate and timely information on changing weather patterns. Estimates were then made of the potential savings that could be realized with accurate information about the prevailing weather and short term fore-casts for up to 12 hours. Improved weather information was defined to mean that a satellite observation not more than one hour old was available and was the basis for a current weather description and an accurate 12-hour forecast.

The growing, marketing, and processing operations of the twenty most valuable crops in the United States in 1971 were studied to determine those operations that are sensitive to short-term weather forecasting. Agricultural extension specialists, research scien-

tists, growers, and representatives of processing industries were consulted. Statistics from the U.S.D.A. Crop Reporting Board show that the value for farm crops produced in the United States was more than 26 billion dollars in 1971. The total value for crops surveyed in this report exceeds 24 billion dollars and represents more than 92 percent of total U.S. crop value.

A detailed study was made of the operations in the production and processing of vegetable crops to obtain precise estimates of the value of improved weather information. Vegetable processing industries of the North Central Region (Wisconsin and Minnesota) were contacted through the Wisconsin Canners and Freezers Association and a special weathercasting subcommittee was established. Meetings were held with industry personnel representing six large processors in these states to determine aspects of their operations that could be improved with more precise weather information and to develop procedures for estimating the value of this information. The company representatives utilized their field and processing plant records to determine losses resulting from unfavorable weather and to provide estimates of the savings that could have been realized with accurate short-term weather information. The entire agricultural process was considered in the survey from soil preparation and pesticide spraying operations to the harvesting of crops and the delivery of field products to consumers or food processors.

This survey of agricultural crops has indicated that improved weather information would have saved crop growers and processors $74,000,000 in 1971. Short-term forecasts from satellite data are of particular value for crops which yield perishable products and which require very precise production practices in order to insure marketability. The annual weather related loss in agriculture in the U.S. is estimated to be $12 billion. It is estimated that protectable losses through improved 3-5 day weather forecasts average about $5 billion per year. Regional agricultural advisories issued by the National Weather Service (NWS) are responsible for saving approximately $400 million per year in the NWS Western Region alone. These regional savings include:

- Raisin crop drying - harvest vs. cover - California ($800 million/year potential loss)
- Water removal from ripe cherries using helicopters ($124 million/year protectable loss)
- Grape harvest - Monterey County, California ($79 million/year bonus)
- Frost protection - Arizona ($500/acre savings)

- Planting impact in Washington State
  ($70 million/year savings)

- Weed and pest control - cost to re-spray due to rain washoff
  ($8-$10/acre)

In 1980, specially enhanced AVHRR data were used in a novel way to solve an agricultural problem in California. A local bee breeder, with the intention of relocating and expanding his operations, asked the San Francisco SFSS for help in determining the warmest daytime areas during the months of January through March. Warmer daytime temperatures increase bee activity. TIROS-N/NOAA-6 AVHRR IR images over the three-month period were enhanced to accentuate afternoon ground temperatures. Persistent warm areas were then located in the desirable counties, and these data were superimposed on maps detailing favorable bee habitats. Once an optimum correlation was made, the bee breeder contacted the land owners for possible rental space for the beehives.

B. Citrus Industry

When frost is expected in Florida on cold winter nights, the NOAA Satellite Field Services Station (SFSS) in Miami, Florida, provides specially enhanced GOES infrared images and interpretations to the National Weather Service which has responsibility for fruit frost forecasting. This capability was first successfully demonstrated in January 1976 and became an operational program during the winter of 1976-1977.

The enhanced satellite images show surface temperatures which are critical to freeze predictions. These ground temperatures, derived from images taken every 30 minutes over the entire southern citrus belt, are accurate within $\pm$ 1°C. Thus, the movement southward of the cold winter air and associated "freeze line" can be monitored and tracked every half hour. The Weather Service provides the observations and forecasted movement of the cold air to the citrus growers as soon as it is available.

The Florida citrus grower must decide whether or not to protect his crop upon receiving a forecast for temperatures below about 28°F. These protective actions usually include the firing of diesel heaters and/or the use of electrically operated wind machines. The grower must decide when to call in work crews, when to activate heaters and/or wind machines and how many heaters must be used. All of these decisions affect their operating costs and losses incurred from inadequate protection.

Protecting citrus groves is a very expensive operation, and needless heating can produce an exorbitant waste of fuel. There are approximately 750,000 citrus-bearing acres in Florida. On

"cold" nights, an average of 6 hours of heating protection is needed at a cost of approximately $830,000 per hour for fuel. This amounts to a potential $5,000,000 cost per night for the state of Florida if smudge pots and other frost prevention devices are operated because of expected temperatures near the freezing mark. The cost to have labor on duty waiting for specific satellite aided fruit frost warnings before lighting smudge pots and operating frost prevention devices is about 42¢ per acre or $315,000 per hour. Thus, the net potential savings for timely and accurate satellite freeze line forecasting is $515,000 per hour.

It is estimated that 1 to 2 hours of heating protection per "cold" night could be saved as a result of the use of the frequent satellite imagery. Assuming a reduction of 1½ hours average heating protection, the savings could amount to $770,000 per cold night. During the winter of 1976-77, a total of 64 cold nights were experienced. During the winter of 1977-78, 54 cold nights were experienced in the state of Florida. The average number of cold nights in Florida each winter is 35 to 40. The enhanced satellite images are used routinely to observe the movement of the "freeze line" to warn citrus growers via NOAA Weather Radio and a telephone communications network via county agricultural agents. The satellite enables a greater amount of temperature information to be acquired more frequently and passed on to the citrus growers in a timely manner.

The NOAA Satellite Field Services Station (SFSS) at San Francisco prepares a daily satellite image interpretation narrative tailored to the needs of the National Weather Service (NWS) fruit frost forecasters. Frost sensitive agricultural products grown in California amount to $3.7 billion per year. Advisory committees have estimated that the frost forecasts provided by the NWS are responsible for saving between 5 and 20 percent. The fruit frost forecasters have estimated that the satellite contribution to this savings of harvests would be between 0.5 and 1.0 percent, or between $15 and $40 million annually.

C. Hawaii Sugar Cane Industry

The harvesting of sugar cane is a process which is very dependent upon local weather conditions and benefits greatly from satellite derived forecasts. The Waialua Sugar Company on the island of Oahu has been using satellite imagery provided by the NOAA Satellite Field Services Station in Honolulu, Hawaii, to plan their harvesting schedule.

When a cane field is ready for harvest (about 2 years after planting), it is first deliberately set on fire and burned; the remains are then gathered and hauled to the mill. Weather is an important factor in this complex operation. Convection and trade

wind showers are the main weather hazards to the harvesting process. Burning must abide by State and Federal air pollution regulations. Tactical procedures for burning a particular field depend heavily on wind direction and speed. After burning, the remains must be harvested within 24-36 hours to avoid spoilage. Any significant rainfall during this critical period interferes with the movement of heavy harvesting vehicles in and out of the field. Typically, 50 to 100 acres are burned at one time, leaving burnt cane worth $250,000 lying in the field at the mercy of the weather.

The production manager of the Waialua Sugar Company, who is responsible for making the daily harvesting decisions, has said, "I look at the weather maps and listen to what they are saying on the broadcasts, but when I look at the satellite pictures, I can really see what's coming." Their company has about 15,000 acres under cultivation. Over a typical harvest season from September to December, the daily weather related decisions must be based on the most accurate information available if costly mistakes are to be avoided. The availability of satellite pictures helps reduce the odds in an operation where mistakes are measured in millions of dollars. The estimated savings of the Waialua Sugar Company alone as a result of using satellite data is $1,000,000 per year.

D. Crop Monitoring

The polar orbiting NOAA satellite's Advanced Very High Resolution Radiometer (AVHRR) Channel 1 and 2 data are used by a variety of national and international agencies for crop monitoring purposes. Some of these are:

a. U.S. Department of Agriculture Crop Commodity Assessment Division (CCAD) uses AVHRR data to monitor yields internationally including Russia, Australia, Argentina, India and Canada. Crop yields in these nations can have a direct impact on commodity prices in the United States. CCAD has been receiving about five AVHRR tapes daily from NOAA since May 1981. These are sent via air express from NOAA/NESDIS headquarters in Suitland, MD, to the Johnson Space Center (JSC) in Houston, TX. The data generally arrive at JSC for operational analysis by CCAD within 48 hours of a satellite overpass. Annual cost of the tapes to CCAD is as follows: 5 tapes daily x $72 per tape x 365 per year = $131,400 (annual cost). CCAD receives Landsat data for these same areas via the JSC-GSFC satellite (DOMSAT) link. In the past, Landsat-3 data arrived 6 weeks after overpass, but CCAD's only costs were for time on the link. In 1983, CCAD will receive the Landsat 4 data within 48 hours, but at a cost of almost $1000 per scene. Prior to 1981, CCAD used 15,000 Landsat scenes yearly. Users will obviously have

to balance their budgetary resources, need for geographic coverage and need for the highest resolution data available to obtain the proper Landsat MSS vs. NOAA AVHRR mix.

b. The United Nation's Food and Agriculture Organization (FAO) uses NOAA AVHRR data in several projects some of which are listed below:

- The Sud area in Sudan - monitor agriculture development activities in an area which experiences yearly flooding from the Nile.
- Kenya - country-wide agricultural land use assessment
- Zambia and Botswana - monitor grazing lands and large scale land use changes.
- Lake Chad area (Niger) - monitor agricultural activity surrounding the lake

4. Search and Rescue Operations

Satellite pictures provided by the National Environmental Satellite, Data, and Information Service (NESDIS) assist in search and rescue (SAR) planning throughout the United States inland SAR area. The satellite data are coordinated through the Air Force Rescue and Coordination Center (ARFCC) located at Scott Air Force Base, Illinois. The USAF Aerospace Rescue and Recovery Service provides coordination of air searches throughout the United States. When an aircraft is overdue, the AFRCC must obtain the routing of the aircraft, determine if weather might be a factor, check on the missing pilot's qualifications and have a knowledge of the performance capabilities of the missing aircraft.

Most search and rescue missions conducted over the enroute phase of flight have shown that missing general aviation aircraft encountered unexpected weather along their route. Pilots who obtained weather briefings prior to departure in which good VFR flight conditions were forecast, encountered narrow bands of unreported weather which can be seen on satellite imagery. If an aircraft is reported missing, areas of severe weather can be located with satellite imagery showing conditions at the time the pilot was in distress. These pictures assist in determining if certain preferred mountain routes were open or blocked by hazardous weather. The height of the cloud tops can be determined to see if the missing pilot could fly over the storm system or was faced with staying at lower altitudes and trying to get through the weather.

The statistics for missing general aviation aircraft that were lost on the enroute phase of flight over three years are discussed below. These are incidents in which the USAF Aerospace Rescue and Recovery Service (AARS) responded with search and rescue service. During the period 1975 through 1977, a total of 747 aircraft were lost. A total of 1,679 persons were aboard these aircraft of which 1,008 were killed and 671 survived. Based on the analysis of satellite imagery of the crash sites, the AARS and the California Wing of the Civil Air Patrol (CAP) believe that weather was a factor in more than 85% of these aircraft accidents. A ten-year study of aircraft accidents by the National Transportation Safety Board (NTSB) for the period 1964-1974 without analysis of satellite imagery, indicated that weather was a factor in only 25% of the accidents.

The California Wing of the CAP began utilizing satellite photos obtained from the NOAA Satellite Field Services Station in San Francisco for SAR in October 1974. By mid-1975, it was apparent that satellite data were a new timesaving aid in locating missing aircraft. During this test period, 58 search missions were conducted and only two searches exceeded 48 hours. During the previous year, 46 search missions were conducted and CAP pilots averaged more than a week searching for the crash sites. Search missions of 24 to 48 hours are now common as opposed to several days to two weeks without satellite data .

During the period 1975 through 1977, a reduction of 32% in total SAR flying hours was realized by the USAF ARRS and the CAP. However, at the same time, the number of SAR missions actually increased by 14%. Following the introduction of satellite data to SAR operations, for the first time in the history of rescue service, the number of flying hours actually decreased. The following table lists the number of CAP missions, hours flown, and average hours per mission for a seven year period.

Civil Air Patrol Mission Summary (1971-1977)

Year	Number of Missions	Hours Flown	Average Hours per Mission
1971	389	30909	79.5
1972	348	27391	78.7
1973	429	27284	63.6
1974	460	21773	47.3
1975	694	24500	35.3
1976	817	17064	21.6
1977	896	16004	17.9

38-036 O - 84 - 30

Satellite support of search and rescue was introduced in 1974, tested in 1975, and has been used extensively since 1976. The mission summary table above shows a marked decrease in average hours flown per mission. Between 1974, immediately before the launch of the SMS satellite, and 1977, the average number of hours flown per search and rescue mission has decreased by 62%. With the average cost of $36 per hour for fuel, oil and maintenance (CAP manpower is entirely voluntary), these reductions result in an annual savings of $344,000 for CAP search and rescue operations. USAF ARRS C-130 SAR mission hours were reduced by 7000 hours for both 1976 and 1977. At $995 per hour, this results in an annual savings of $6,965,000 for C-130 time alone. Thus satellite data, available on an operational basis, has annually saved several million dollars in tangible benefits and has produced untold intangible benefits in reductions of human suffering and death through the faster location of missing aircraft.

5. Ice Monitoring

Shipping operations in the Arctic, Great Lakes, and St. Lawrence Seaway are obviously greatly affected by sea, lake, and river ice. The National Environmental Satellite, Data, and Information Service provides support during the ice season to the U.S. Coast Guard International Ice Patrol. The satellite ice analyses are also extremely valuable to ice reconnaissance aircraft in Canada as an aid in pre-flight planning and in locating areas of improved visibility. This has resulted in increased efficiency in the visual reconnaissance missions producing a savings of about 1500 aircraft flight hours and related cost reductions of about $5,000,000 annually.

The Canadian Centre for Remote Sensing (CCRS), Department of Energy, Mines and Resources has shown that imagery indicating the presence and extent of sea ice has been very useful and cost effective to geophysical survey ships engaged in seismic surveying off the north coast of Canada in the Arctic Ocean. AVHRR images are routinely received by the Atmospheric Environment Services Receiving Station at Downsview, Ontario.

Seismic operations for oil and gas exploration in the Bering Sea, Norton Sound, Chukchi and Beaufort Seas have relied heavily on satellite observations. Because of the competitive nature of this activity, information is proprietary, but exploratory companies involved indicate that the satellite data are used as a planning tool to lay out cruise tracks that save time and fuel and minimize damage by ice to non-ice reinforced ships and testing equipment. The presence of any floating ice makes seismic sounding impossible. In one instance, an area scheduled for survey was found to have free floating ice fragments. Advice was sought by a geophysical survey ship from the CCRS which redirected the ship to a nearby area (100 n.mi. away) where ice-free conditions were

interpreted from the daily satellite imagery. As a result, the ship was able to acquire twice the amount of data normally gathered. In this instance, the single image saved $250,000.

In another other example, the ARCO Oil Company used NOAA satellite imagery in 1979 to monitor ice conditions near Alaska. ARCO was using a drilling ship designed for use in the Gulf of Mexico for exploratory ice drilling in the lower Cook Inlet. By using the satellite data, ARCO was able to save $45,000 in insurance premiums on this project. A more recent example of the use of satellite data to monitor ice conditions in support of offshore drilling operations occurred in January 1983. The ARCO Oil Company was using the "Gulf of Mexico" jack-up rig drilling an exploratory well north of Port Heiden in the Aleutians. Extremely cold temperatures and a strong north wind began moving the ice front towards the rig at 25-30 miles per day. NOAA satellite imagery and analyses of the ice were provided daily by the Anchorage SFSS to the Minerals Management Office, U.S. Coast Guard, ARCO and the media. The rig was eventually evacuated and towed to safety based almost entirely upon the real-time analysis of the polar satellite imagery. Sacellite ice observations also play an important role in the Arctic regions for the U.S. Fish and Wildlife Service monitoring of marine mammals' (walrus, whales, seals and polar bears) migration patterns.

In the Great Lakes, satellite imagery is used to find navigable waters for shipping as long as possible into the winter season. The high resolution satellite images show small ice free areas which can be used by ships to continue operations longer than previously possible. It is estimated that the extension of the shipping season by this method results in a cost benefit of $1,000,000 per day for each day extended. Before the use of satellite data, the Great Lakes were closed to shipping for about 2 months each winter. In the winter of 1976-1977 which was exceptionally bad, the Lakes were closed to shipping for only 1 month and during the 1977-1978 winter, they were never completely closed. In this case, however, it is incorrect to attribute all of the savings to satellites alone, since the use of side-looking radar (SLR) on reconnaissance aircraft was introduced in the same time period. Nevertheless, satellites could contribute to annual savings of as much as $30 million.

Satellites are also used to provide early warning of river ice melting and break-up, which could cause ice jams and flooding. Hydrologists require timely information on the progress of river ice break-up during spring thaws. Ice jams often cause severe flooding and threaten hydroelectric plants, bridge piers, and ship navigation. As an example, in 1977, NOAA scientists closely monitored the Ottawa River in Canada using visible images from NOAA's polar orbiting satellites. They were able to view the day-to-day changes in break-up and melting of the ice.

6. Snow Cover Mapping

The use of satellite acquired data for mapping snow cover has proven valuable in water resource planning and flood forecasting. Snow covered area estimates from operational NOAA satellites have proven to be much faster and more economical than conventional aerial surveys. Snow and ice cover a significant portion of the earth's surface. For example:

1. Snow covers 30-50 percent of the land area.

2. Ice covers about 25 percent of the oceans.

3. Glaciers cover about 10 percent of the land area.

4. Permafrost covers 10 percent of the land area.

Frequent observations of the extent and characteristics of snow and ice are needed to assist many industries in their day-to-day operational requirements. Some operational requirements which are especially affected by snow are (1) flood warning systems, (2) municipal and regional water supply management, (3) irrigation systems management, (4) hydroelectric power management, (5) energy requirements, (6) transportation systems operations, and (7) food supply requirements.

For example, satellite snow cover analyses were used in 1976 while a storm was still in progress to determine that it would not be necessary to spill the Verde River reservoir system in Arizona as had been previously planned. Spilling of the reservoirs would have put water into the normally dry Salt River channel above Phoenix which causes road closings and local flooding in the Phoenix metropolitan area and results in the loss of valuable irrigation water. The dollar savings were considerable. In addition, continental snow cover has important climatic impacts on surface and air temperature, radiation balance, soil moisture, cloudiness and precipitation.

Mr. Donald R. Wiesnet, former hydrologist with the National Environmental Satellite, Data, and Information Service, has shown that satellites have made a significant contribution in snow cover mapping where the cost ratio between the satellite and conventional aerial survey is as much as 200 to 1 in favor of the satellite. For example, it takes about 40 hours of flying at $500 per hour to map 20 river basins in the Sierra Nevada mountains. Thus, it costs about $20,000 per aerial mapping operation which is done several times during the winter and spring, funds permitting. When cloud free conditions are available, this job can be accomplished using satellite data in about two man-days at a cost of $200. Thus, annual savings in mapping the Sierra Nevada basins alone could be as much as $1,000,000.

In the mountainous regions of the United States, millions of dollars are spent each year to measure snowpack at fixed locations for forecast purposes. In 1969, a panel of scientists from the National Academy of Sciences states, "The changing extent, surface temperature, thickness, water equivalent, and liquid water content of seasonal snowpack are necessary for engineering design and operation and planning of water projects large and small. In the mountain areas of the United States, millions of dollars are spent each year at fixed locations to measure snowpack for forecast purposes. Improved forecasts are estimated to be worth $10,000,000 to $100,000,000 per year to water users in the western United States alone." Operational environmental satellites can contribute greatly to improved hydrological forecasts.

Seventy percent of the runoff in the western United States is derived from melting snow. In a study funded by the National Science Foundation, it was found that increased cloud seeding in the upper Colorado River basin could result in snowpack augmentation with $12.8 million annual benefits.

NESDIS began operationally producing satellite snowcover maps for 30 selected western U.S. river basins in the spring 1974. The snowcover data are used in river runoff models, dam and reservoir release decisions, and are input to seasonal water supply forecasts to determine how much water is available for irrigation, hydroelectric power generation, municipal consumption, and recreation. About 600 river basin snow maps are produced annually; data are relayed to users via teletype, telecopier or through the mail. Agencies involved as subscribers to this satellite service include the U.S. Forest Service, Soil Conservation Service, Army Corps of Engineers, Bonneville Power Administration, National Weather Service, Bureau of Reclamation, Bureau of Land Management, and the U.S. Geological Survey.

In the late 1970's, the National Aeronautic and Space Administration (NASA) initiated a four year (1975-1979) effort to evaluate the usefulness of satellite snowcover information for water resource managers. The project was identified as the snowmapping Applications Systems Verification Transfer (ASVT) project. Volume VII of the project's final report addressed cost/benefit aspects of the snow study. It was found that:

a) The improvement in runoff prediction due to the addition of satellite information is 6-10%.

b) Benefit models developed for irrigation and hydroenergy uses revealed savings of $36.5 million yearly when satellite snowcover data were supplied for river basins throughout the western United States. The cost of such a satellite snowmapping program was determined to be $505K, thus yielding a benefit/cost ratio of 72:1.

7. Natural Disaster Warning

Environmental satellites have been very effective in providing data for improved natural disaster warnings. It is however, very difficult to correlate lives and dollars saved during a disaster directly to improved forecasts and warnings. NOAA satellites provide environmental data to forecasters and government officials regarding tornadoes, severe thunderstorms, hurricanes, tropical storms, flooding, severe winter storms and other less destructive environmental phenomena. Satellite data are transmitted around-the-clock, 7 days-per-week to the various National Centers for environmental warning including: the National Severe Storms Forecast Center (NSSFC) in Kansas City, Missouri; the National Hurricane Center (NHC) in Miami, Florida; the Eastern Pacific Hurricane Center in San Francisco, California; and the Central Pacific Hurricane Center in Honolulu, Hawaii.

A. Hurricane Warning

Satellite imagery is used extensively in monitoring tropical storms and hurricanes. Several years ago, aircraft reconnaissance was the primary method of finding and tracking dangerous tropical storms in the oceans. Increasing costs of petroleum, maintenance and manpower have caused a drastic cutback in tropical storm reconnaissance by the U.S. Air Force and NOAA. The satellite observations have practically replaced all storm reconnaissance except when a hurricane is approaching land. The cost of aerial reconnaissance is about $2,500 per hour and the average mission requires at least 10 hours. Thus, there is a potential savings of $25,000 per flight for every reconnaissance flight avoided by the use of satellite data. In addition, the satellite imagery has enabled the aircraft storm reconnaissance to be more efficient and cost effective in plotting flight tracks for data gathering due to improved navigational information about the location of tropical cyclones.

Since the inauguration of the operational satellite system, no tropical storm goes undetected, even in the most remote areas of the world. The GOES-E spacecraft acquires an image every 30 minutes around-the-clock of the North Atlantic Ocean, the Caribbean Sea and the Gulf of Mexico providing excellent tropical storm detection and monitoring capabilities. Hurricane reconnaissance aircraft no longer have to fly random search patterns over the vast tropical oceans to locate storms which may be developing there. Estimated savings from using satellite storm detection and monitoring in mid-ocean in place of expensive aircraft reconnaissance are about $1,800,000 annually.

The information listed below illustrates the magnitude of hurricane destruction in terms of dollars and fatalities.

Hurricane Fatalities and Damage (1900 - 1982)

Year(Period)	U.S. Fatalities	U.S. Damage ($ Millions)	
1900-1904	6000	N/A	
1905-1909	2200	N/A	
1910-1914	100	N/A

*Hurricane Iwa damage assessment was not completed at the time this paper was written. Hawaii had not been struck by a hurricane in 23 years.

The most damaging individual hurricanes by name and year are listed below:

Costliest United States Hurricanes of Record

Name	Year	U.S.Damage ($)
Frederic	1979	$2,300,000,000
Agnes	1972	2,100,000,000
Camille	1969	1,420,700,000
Betsy	1965	1,420,500,000
Diane	1955	831,700,000
Eloise	1975	550,000,000*
Carol	1954	461,000,000
Celia	1970	453,000,000
Carla	1961	408,000,000
Donna	1960	387,000,000
David	1979	320,000,000

*Includes $60,000,000 in Puerto Rico

The damage estimate of $2.3 billion makes Hurricane Frederic the costliest hurricane ever to hit the United States, exceeding the $2.1 billion cost estimated for Hurricane Agnes in 1972. Five deaths were attributed directly to Hurricane Frederic in the United States, only one of which occurred along the coastal region when a person was swept off a boat near Pensacola, Florida. The insurance industry estimated insured losses of $750 million for Hurricane Frederic. Approximately 250,000 persons were evacuated in advance of Frederic.

A 1975 NOAA Technical Memorandum entitled, A Statistical Study of Tropical Cyclone Positioning Errors with Economic Applications by C.J. Neumann noted that until 197[illegible], the initial position error for storms within 500 n.mi. of the coast averaged 22 n.mi., and landfall forecasts were made from distances no more than 300n.mi. A positioning error is defined as the difference between the forecaster's assumed initial position of a storm and the actual position as determined from a postanalysis.

The issuance of hurricane warnings along a portion of the United States coastline is generally accomplished 18 to 24 hours prior to the expected arrival of the storm at the coast. This particular time interval has been found to be an optimized trade-off between the desire to provide maximum warning lead time and the ability to keep the size of the warning area within reasonable limits. With such a lead time, the length of the warning zone averages nearly 300 n.mi. Inasmuch as the swath of damaging winds is generally less than 100 n.mi., the public must expect a minimum overwarning area of about 200 n.mi.

The study includes an economic analysis of potential changes in the size of hurricane warning areas. It is estimated that protection costs (including losses due to temporarily curtailed production) for a typical 300 n.mi. Gulf of Mexico coastal hurricane warning zone total $25.1 million. A 10 n.mi. increase in positioning error will increase this economic loss by about $5 million per storm. A 10 n.mi. decrease in positioning error will decrease protection costs by about $2.75 million per storm. Since an average of about two hurricanes annually move inland on the continental U.S., using the above figures, $50 million is the average annual cost of protection. As a conservative estimate, a reduction of only 5% in the coastal warning area would mean an average annual savings of about $2,500,000 per year. Satellite observations play a major role in keeping the warning area to a minimum.

B. Global Tropical Storm Monitoring

NOAA polar orbiting satellites are used to monitor tropical storms worldwide in addition to those near or endangering the United States. The following table lists the number of named tropical cyclones monitored and tracked by NOAA satellites in three remote ocean areas of the world.

Satellite Monitored Named Tropical Cyclones

Year	West Pacific Ocean	South Pacific Ocean	Indian Ocean
1974	38	12	26
1975	27	8	33
1976	27	10	27
1977	21	10	23
1978	27	7	23
1979	27	6	20
1980	27	8	20
1981	28	12	19
1982	27	9	21

When these storms are detected and tracked by polar satellite, a Satellite Weather Bulletin is sent directly to the meteorological agency of the countries which could be affected by the storm. These bulletins are transmitted daily throughout the life of the tropical storm which averages 8-10 days. In the highly populated countries of southeast Asia, this satellite tropical storm warning service could save many lives if the capabilities to disseminate the warning to the general public were available. Unfortunately, in many cases, the populace does not receive the warnings due to the lack of adequate communications facilities and the death toll has not reflected the availability of these timely warnings.

C. Severe Thunderstorm and Tornado Warning

Satellite imagery is a primary data source for the National Severe Storm Forecasting Center (NSSFC) in Kansas City which has severe thunderstorm and tornado forecasting responsibility for the continental United States. In 1972, the NESDIS established a Satellite Field Service Station (SFSS) collocated with the NSSFC. The Kansas City SFSS has been instrumental in developing new techniques in applying satellite imagery to severe storm forecasting. The use of high resolution GOES visible and enhanced infrared imagery taken at frequent intervals (as often as every 15 minutes) has been extremely useful in monitoring the development of severe thunderstorms. This satellite capability has enabled NSSFC forecasters to pinpoint areas with a high probability of a tornado so as to reduce the area of warning. By reducing the area of warning, the "cry-WOLF!" attitude that sometimes exists toward tornado alerts will be lessened. The satellite has been instrumental in accurately defining the tornado watch areas which are provided to the news media and NWS forecast offices.

The following table lists the fatalities and property loss statistics for the period, 1972 through 1982.

TORNADO SUMMARY (1972-1982)
Property Loss Frequency*

Year	Number of Tornadoes	Fatalities	Category 5	Category 6	Category 7 and over
1972	741	27	100	28	1
1973	1102	87	219	67	9
1974	947	361	166	82	25
1975	920	60	189	31	11
1976	835	44	145	41	5
1977	852	43	173	40	6
1978	788	53	153	53	6
1979	852	84	169	62	11
1980	866	28	205	79	13
1981	782	24	144	43	12
1982	1028	64	N/A	N/A	N/A

*Number of times property losses were reported in storm damage Categories 5, 6, 7 and over.

Property Loss Category Definitions

Category 5	$50,000 - $500,000
Category 6	$500,000 - $5 million
Category 7	$5 million - $50 million
Category 8	$50 million - $500 million
Category 9	$500 million and over

The above losses are based on estimated values at the time of occurence.

As shown in the table above, the cost of damage has risen significantly in recent years due to more populated areas being hit by tornadoes and increased building costs due to inflation. Because tornadoes and severe thunderstorms are relatively small scale and short lived, it is difficult to prepare to protect property in a manner similar to that which is done with the larger scale and slower moving hurricanes. It is currently impossible to predict the exact time and locations these severe storms will arrive, but satellite images provide an indication of the development of the type of meteorological situations in which these storms occur. Unfortunately, satellite observations of tornadoes and severe thunderstorms can do little to aid in reducing the amount of property damage sustained. It is significant, however, that there has been a notable reduction in the average number of deaths since 1975.

Beginning in 1975, GOES data has been a significant and heavily used input to the NSSFC. It seems clear that there is a correlation between the lower number of lives lost since 1975 and the introduction of operational geostationary satellite data into the severe storm forecasting and warning process. Even excluding the April 3rd calamity of 1974, an average of 84 fatalities per year occurred between 1968 and 1974. The average number of deaths since satellite data has been extensively utilized is 50 fatalities per year.

The New Orleans SFSS plays an important role in reducing the element of surprise of severe weather sweeping in from the Gulf of Mexico and overtaking mariners, offshore oil workers and coastal residents. During this century alone, 21 hurricanes have come ashore from the Gulf killing hundreds of persons and causing billions of dollars in damage. In addition, scores of tropical storms and winter-time cyclones have hit the Gulf coast areas. Although not as severe as hurricanes, these storms cause extensive damage and threaten the lives of those individuals who use the Gulf for their livelihood and recreation.

With the advent of the energy crisis, emphasis has been placed on offshore oil drilling and production activity. The magnitude of this effort is reflected in the following statistics. There are 1,249 production platforms with heliports, approximately 240

drilling rigs on location, and 28,000 individuals working offshore. To support this vast and complex industry, approximately 700 helicopters (flying an average of 25,000 hours per month) transport 150,000 passengers each month from bases located along the Texas and Lousiana Gulf coast.

The New Orleans SFSS focuses on small-scale meteorological events in an area extending from 90 miles onshore to 200 miles offshore. Special attention is given to the thunderstorms and squall lines which develop rapidly throughout the Gulf with little advance warning. When these storms are detected, the SFSS issues advisories to National Weather Service Offices and other government agencies along the Gulf coast.

D. Flood Warning

Satellite data also have been valuable in providing early warning for floods. An example is the September 13, 1977 flood disaster in Kansas City. Information provided by the NESDIS SFSS in Kansas City to National Weather Service Forecast units prior to and during the Kansas City flood was timely and accurate. The early recognition of the precipitation boundary which had been left by the previous night's thunderstorm activity in northern Missouri identified a meteorological mechanism which had potential for initiating new thunderstorm development over an area where the ground was already saturated. This satellite information, when incorporated with other data, contributed to the NWS decision to issue a local forecast early in the day for heavy rain. Later satellite data provided information which was instrumental in the issuance of a severe thunderstorm watch which included the Kansas City metropolitan area. The satellite evaluation gave new information concerning the southward shift of the axis of thunderstorm development, and coupled with supporting evidence from the NWS radar, suggested the potential for heavy rain in the Kansas City area.

An example of satellite contributions to international flood warnings occurred in August of 1977 when United States satellite assessments of snowpack were used as an indicator of flood potential in Pakistan. NOAA-5 VHRR coverage was especially programmed to include the Himalaya Mountains. Two large river basins in the Himalayas were monitored: the Indus River above Besham (162,100 km^2) and the Kobal River above Nowshera (88,600 km^2). A late snow melt in the Himalayas could have greatly increased the potential for flooding in Pakistan. Percent snowcover as derived from the satellite was compared with historical data and transmitted to the Pakistani Ambassador in Washington, D.C.

Satellite data is very beneficial in flash flood forecasting. During the period October 12-13, 1981 excessive rainfall occurred over Texas and Oklahoma. The primary ingredient for this episode was a dying tropical storm (Norma) which was moving out of Mexico.

Numerical forecast models, due to the scarcity of data over Mexico, were unable to forecast its movement. The first hint of this feature moving toward Texas came from satellite derived data. This information prompted the issuance of twenty Flash Flood Watches in various parts of Texas. As the system moved into Texas, triggering copious rains, Quantitative Precipitation Estimates based on satellite images were provided to numerous NWS offices. There were four major floods during 1982. Flooding in Fort Wayne, Indiana, New England, Louisiana and the central Mississippi valley claimed 150 lives and caused damage in excess of $2 billion.

8. Large Scale Weather Forecasting

NOAA operational environmental satellites contribute greatly to the National Weather Service's National Meteorological Center (NMC), the central weather analysis and prediction facility for the United States. At NMC, which is also a World Meteorological Center, observations from all over the globe including satellite data are collected, processed by computer, and used to produce maps of existing and predicted weather conditions. In a 24-hour period, the NMC receives about 42,000 approximately 50,000 satellite observations. Maximum benefits from satellite data are realized when this information is effectively used to bridge the gap in time and space between conventional meteorological observations. A synthesis of all types of meteorological data such as satellite, surface, upper air, radar, etc., results in a more complete and accurate understanding of atmospheric processes.

Dr. Robert M. White, former Administrator of NOAA, discussed the role of satellite data in large scale weather applications in an article in The Military Engineer (July-August 1973) entitled Environmental Satellites - A Progress Report. In this article, he wrote the following:

"The World Meteorological Center, Washington, D.C. (the other World Centers are in Moscow and Melbourne) uses photographs, temperature soundings, and wind measurements acquired by satellite to improve the accuracy of large scale weather analyses and forecast weather charts. These charts are communicated by facsimile circuits to civil and military weather stations in the United States and become part of the guidance material given to field stations for use in weather forecasting. Air Force and Navy weather centrals receive both direct and processed data for use in similar ways. Analysis centers, which provide special services to agricultural, hydrological, engineering, maritime, and other interests, use satellite data routinely in the preparation of their products. Several factors make satellite data unique in comparison with data acquired from other sources. A major characteristic is that, because of its vantage point above the atmosphere and its broad field of view, the satellite can provide information regularly for vast areas of the globe where data from other more conventional

sources are sparse or unobtainable. This coverage of the large data gaps over oceans and remote land areas is one of the basic and most important contributions of satellites to improved weather forecasts. Also important is the immediacy of data transmitted directly from satellites to ground stations. Such data frequently are received and put into use some hours before routine data are received through normal communications channels. The third characteristic is the broad view of earth and atmospheric features that can be obtained only from satellite altitude. Large-scale weather systems can be seen in a single view, whereas the definition of atmospheric or sea surface conditions obtained from aircraft or groundbased observation is incomplete."

The environmental satellite is an excellent global observational platform and the United States freely contributes data from its satellites to the world meteorological community. Satellite data is an important part of the World Weather Watch Program of the United Nations' World Meteorological Organization. The direct readout systems (APT and HRPT) from the polar orbiting spacecraft and the WEFAX transmissions from the geostationary spacecraft are used by more than 123 countries around the world.

Thus, environmental satellites contribute significantly to large scale weather observation and forecasting. Deriving the actual cost benefits of such services is extremely difficult, if not an impossible task. This is because the only way of obtaining these benefits would be to compare the cost of information obtained via satellite with what it would cost to acquire comparable data via conventional means (e.g. surface observations, radiosonde, radar and meteorological buoys). Not only would the acquisition costs be prohibitive, but it would be physically impossible to obtain this large amount of diverse data in a timely manner. The value of satellite acquired observations to global scale forecasting is certainly several millions of dollars annually.

9. Miscellaneous Activities

There have been many uses of environmental satellite data some of which are significant and others which have no measurable economic benefit at present, but may have in the future. This section briefly discusses some of these activities related to the utilization of environmental satellite data.

A. Airline Fuel Savings

The NASA Lewis Research Center completed a 20 month study in 1981 regarding the value of improved upper air wind and temperature forecasts to the worldwide commercial airline industry. This study was discussed in a paper entitled Airline Flight Planning - The Weather Connection by Robert Steinberg in April 1981.

In his paper, Mr. Steinberg reviews the meteorological basis for the present method of airline flight planning and analyzes its impact on current flight operations. He suggests a new approach for developing a weather base for flight planning which has the potential of providing fuel savings of 2 or 3 percent on long distance flights.

Mr. Steinberg suggests that a meteorologist, using man-computer interactive techniques, could develop an accurate upper air nowcast (3-12 hours) using the NWS synoptic numerical forecast, satellite data, rawinsonde and pilot reports. Satellite data is the most timely and also provides information on the location of jet streams, which is very important. This nowcast would provide the basis for automated flight planning by the airline.

Mr. Steinberg estimates that an interactive system with satellite data input to provide upper air tuned forecasts, including manpower for a 24 hour operation would cost about $600,000 per year after a one time capital investment for equipment of about $1,000,000. An international carrier with a present fuel bill of one billion dollars could expect to save at least $20 million per year on trip fuel alone. When one considers the potential for optimizing reserve fuel requirements, the savings could even be considerably higher.

B. Game Bird Management

The Office of Migratory Bird Management of the U.S. Fish and Wildlife Service has used NOAA polar-orbiting VHRR pictures to help determine the reproductive success of several species of arctic nesting geese. The Wildlife Service is responsible for annually adjusting hunting regulations to conform with the estimated population of particular species of waterfowl. The waterfowl managers must know well before the hunting season what the supply of game birds will be, otherwise their existence could be threatened by over-harvesting.

The most important factors affecting the reproductive success of arctic nesting geese is the timely disappearance of snow, ice, and the availability of melt water to allow for the production and rearing of young. Late seasons or adverse weather conditions can result in the geese not nesting, reduced brood sizes, or failure to renest. Any of these adversely affects the population. Waterfowl managers, using NOAA's polar orbiting satellites, can monitor habitat snow and ice conditions in the remote arctic nesting areas in a timely and economical manner. The satellites provide visual and infrared images twice daily to help identify areas of catastrophic or outstanding goose production, permitting the wildlife service to establish appropriate hunting regulations.

C. Dust Storm Monitoring

Both the geostationary (GOES) spacecraft and the polar orbiting (NOAA) spacecraft have been used to monitor the development and dissemination of dust storms in the Plains States. For example, in February 1977, these operational satellites detected dust clouds originating in New Mexico and Colorado and tracked them across Kansas, Oklahoma, Mississippi, Alabama and Georgia out into the Atlantic Ocean. The major dust storm was considered among the worst since the "Dust Bowl" days of the 1930's.

Monitoring the development and movement of dust storms is important to the aviation industry, soil erosion and agriculture experts, scientists conducting solar energy research, pollution monitoring specialists, etc. Satellites can be used effectively by meteorologists to monitor major dust storms.

D. Locust Plague Control

Agricultural crops and rangeland resources estimated to be worth 30 billion dollars over some 30 million square kilometers in 60 countries with more than a fifth of the world's population are prone to the ravages by the Desert Locust, Schistocera gregaria. The primary factors which influence the growth and movement of the locust are the temperature and moisture content of the air and ground and the standing crop. These factors can be measured using NOAA environmental satellites and Landsat satellites. NOAA polar-orbiting satellite images have been used by the United Nations Food and Agriculture Organization (FAO) to monitor areas of probable rainfall in northern Africa countries such as Algeria, Somalia, India, and Pakistan. The NOAA satellite images are examined in detail with Landsat images of these areas, enabling U.N.FAO scientists to locate areas of emergent vegetation which is essential for desert locust development. The location coordinates of potentially dangerous areas are relayed to locust control teams in the countries involved. These teams then examine the area and determine if insecticide spraying is necessary to inhibit the development of migratory swarms.

Building further on the results obtained during the Desert Locust/Remote Sensing Pilot Project, carried out by FAO in Northwest Africa in 1976/77, techniques were developed and initially tested for quantitative rainfall monitoring over large areas using environmental satellite data, e.g., Meteosat and TIROS-N/NOAA, and vegetation biomass activity detection and monitoring with Landsat digital data. Vegetation monitoring for the entire desert locust region with Landsat 80 meter-resolution data (MSS Bands 5 (visible) and 7 (near infrared)) requires the processing of huge amounts of data at an extremely high cost. Analysis has shown that Landsat data often has excess resolution for FAO purposes and can be reduced by a factor of 35 and still used effectively.

With the launch of TIROS-N in October 1978 and NOAA-6 in June 1979, 5-channel AVHRR data (including the near infrared) at a resolution of 1.1 Km became operationally available for the first time. Previous NOAA polar orbiting satellites (the ITOS series) had sensors that imaged only in the visible and thermal infrared regions of the spectrum. FAO began exploring the use of AVHRR data in desert locust studies in the summer of 1980 with promising results. Locust breeding grounds in southern Algeria were successfully identified for the first time on AVHRR data of August 31 and September 10, 1981. The data were analyzed on the NASA/GSFC H.P.1000 interactive system. Ground confirmation was supplied through FAO headquarters in Rome.

E. Volcano Monitoring

Ash spewed out from erupting volcanos may remain in the atmosphere for many months posing a threat to commercial aircraft. The ash and dust may also affect the earth's radiation balance and surface temperature and in turn, crop and vegetation growth. The five channel AVHRR data have been used in recent studies to determine height of volcano plumes, plume dispersal, plume composition as well as to map the extent of lava flows and the distribution of volcanic ash and dust on the ground. Information gleaned from the satellite data is then passed to the Smithsonian Institute for inclusion in the SEAN (Scientific Event Alert Network) Bulletin published each month in order to pass needed information to scientists and government officials.

The AVHRR satellite data are analyzed on the H.P.1000 interactive system at the NASA/Goddard Space Flight Center. Information on the volcanic plume height is obtained by reducing the thermal data in channels 4 and 5. The extent of the lava flow can be mapped (while the lava is still hot) by using channel 3. The distribution and amount of dust covering the regional vegetation can be inferred using channels 1 and 2. The following volcanos have been studied extensively by NOAA/NESDIS during the past two years.

Location	Volcano	Dates
Mexico	El Chichon	March 29-April 4, 1982
Java	Galunggung	June 24-July 15, 1982
Soviet Union	Alaid	April 28-May 1, 1981
Iceland	Krafla	February 4, 1981
Iceland	Hekla	April 1981
U.S.A.	Mt. St. Helens	May 18, 1980

A team from the Australian Commonwealth Scientific and Industrial Research Organization (CSIRO) and the Western Australian Institute of Technology have developed a method of tracking volcanic clouds. The Australian team recognized that the volcanic ash would contain a large amount of silica that the infrared radiation band would

38-036 O - 84 - 31

detect. When the clouds begin to disperse, they consist of particles only a few microns across and they attain very high altitudes where they pose a threat to jet aircraft. The ash also merges with other clouds and becomes undetectable in the visible spectrum. The silicates in the ash provide a thermal emission pattern different from other clouds.

F. Metropolitan Planning

The heat emitted from metropolitan areas is measured by high-resolution infrared sensors aboard NOAA's polar-orbiting satellies. The sensing of urban "heat-islands" by environmental satellites is used by metropolitan planners to monitor population growth and industrial development as it occurs. Planners are able to monitor the urban growth by comparing greatly enlarged computer-enhanced satellite images with urban census maps. The satellite imagery supplements and in certain cases may be more cost effective than aerial photographs as a tool in determining the amount and direction of growth of a metropolitan area and for delineating boundaries for future census surveys.

The pattern of a city's heat can be quantified from satellite measurements and monitored annually or on a season by season basis. Even small urban areas can produce noticeable thermal anomalies or heat islands when compared to their surrounding rural environment. A NOAA-5 image of New Hampshire, Massachusetts, and Rhode Island acquired on May 23, 1978 was digitally enhanced by NOAA scientists to study urban heat islands. A total of 17 heat islands were detected ranging from Norwood, Mass. (pop. 32,000) to Boston, Mass. (pop. 625,000).

G. Hydroelectric Power Production

Temperature changes of 1°C or more at customer locations are reflected in electric power demand variations at the servicing hydroelectric facility within four to eight hours. The hydroelectric operator must regulate water flow or bring thermal power units on-line to compensate for these demand variations. Because it requires about four hours to make major water flow adjustments or to add thermal power, large hydroelectric operators invest substantial amounts in establishing well instrumented surface observation networks (temperature, wind, humidity, and precipitation) over their service regions. Observed data are used as the basis for specific area forecasts by the meteorologists supporting the hydroelectric operator.

In 1973, a major hydroelectric operator, the Tennessee Valley Authority, investigated the potential benefit of using satellite data every one or two hours to increase the density of surface temperature observations in order to improve the accuracy of their four to eight hour forecasts. It was concluded that operational efficiencies could be achieved that would result in savings "in excess of 1% of operating costs."

H. Forest Fire Prevention and Detection

The National Weather Service maintains Fire Weather Offices (FWO's) at 17 locations in the western United States: Billings, MT; Boise, ID; Wenatchee, WA; Eureka, CA; Fresno, CA; Los Angeles, CA; Medford, OR; Missoula, MT; Olympia, WA; Pendleton, OR; Portland, OR; Phoenix, AZ; Redding, CA; Reno, NV; Sacramento, CA; Salt Lake City, UT; and Salem, OR. The "official" fire weather season varies by FWO district, but can begin as early as April 1 and end as late as November 15. The FWO's release a daily Fire Load Index (defined on a scale from 1 to 100) for regions throughout the western United States. The higher the index number, the greater the number of manhours needed to contain a fire. With millions of acres to be monitored in the western region and limited resources to accomplish the task, the fire load index serves as the most important tool in determining how these resources will be distributed over the next day, week or even month. Poor weather forecasts can mean thousands of dollars lost when a misrepresentative Fire Load Index is distributed.

The NOAA Satellite Field Services Station (SFSS) in San Francisco, California, releases a daily Fire Weather Satellite Interpretation Message (SIM) to aid the FWO in deriving the proper Fire Load Index. The SIM's include information on rapidly developing thunderstorms, surface wind speed and direction, precipitation duration and type (layered or convective), cloud cover, variations in temperature and humidity, extent of surface inversions and amount of solar insolation.

Also of interest to fire weather forecasters is measuring the changes in plant biomass or chlorophyll density in forest plant life and cultivated fields. The plant biomass is directly related to its moisture level and thus to its susceptibility to burning. The Bureau of Land Management (BLM) and the EROS Data Center (EDC) are initiating a program to utilize NOAA AVHRR channels 1 and 2 data to determine fuel loading conditions in wildfire hazard areas. The AVHRR data are analyzed to make estimates of standing green biomass loading within previously Landsat-mapped wildfire fuel types. These estimates (high, medium, low) shall then be incorporated as part of the BLM Initial Attack Wildfire System data base. Initial spring 1982 test areas were located in southeastern Oregon, northwestern Arizona, and the Fairbanks region of Alaska. If the experiment is successful, this technique will be used operationally in fuel loading models beginning in 1984 for the entire western United States and Alaska.

A final application of NOAA AVHRR data is to monitor the actual outbreak of fires. The third channel on the AVHRR (3.5-3.9 um) is extremely sensitive to high heat sources. These data have been used to identify oil flares, mine smelts, factories, power plants, lava flows -- and wild fires. Some of these targets have been found to

occupy an area that is less than 1 percent of the AVHRR pixel size, thus effectively giving "sub-pixel resolution" for high heat sources in this channel. The NOAA San Francisco SFSS ran a test in the summer of 1981 which involved locating "hot spots" on the channel 3 imagery and sending out precise locations to the Fire Weather Offices. As many as 30 fires were spotted on a single day. The overwhelming majority of fires detected on the data proved to be controlled timber or agricultural burns. However, in several cases the satellite data were used to give first notice of a fire. Field verification was supplied by the U.S. Forest Service, timber companies, and in several cases, the local police.

I. Bowhead Whale Monitoring

The NOAA Satellite Field Services Station (SFSS) in Anchorage, Alaska, supports several agencies with respect to the annual bowhead whale migration. Direct briefings and blowups of polar satellite visible imagery of the area from St. Lawrence Island to Prudhoe Bay are provided to National Marine Fisheries Service. Polar satellite imagery of the coastal sea ice is provided to the Bureau of Land Management Outer Continental Shelf Program. The imagery is used to determine where aircraft observers should fly to count and observe the whales. In addition, ice imagery is supplied to the nine Eskimo Whaling Commissioners of the Alaska Eskimo Whaling Commission who use the imagery as a management tool.

J. Water Quality Monitoring

The effectiveness of NOAA geostationary satellites in water quality monitoring was demonstrated in a recent study of Pyramid Lake. The lake, located northeast of Reno, Nevada, is the largest desert water body in North America with a surface area of 440 sq. km and a mean depth of 40 meters. During the summer of 1978 and 1980, the lake experienced massive precipitations of calcium carbonate (whitings). In each case the lake surface became entirely covered with calcium carbonate within two weeks of the onset of whiting, and it would take several months to regain its normal appearance. GOES data were used daily to map the entire whiting sequence: the growth, distribution pattern, intensity and finally cessation of the phenomenon. As more and more water is diverted for agricultural, industrial and municipal use in the western United States, lakes will become increasingly susceptible to such events. The NOAA satellites provide a timely source of data for monitoring such events.

K. Recreational Boating

Satellite data has been used as a major data source to brief sailboat cruising races for several years. The 1982 Newport to Bermuda Yacht Race was postponed 48 hours based on forecasts of a

sub-tropical storm being monitored by NOAA satellites and conventional data. Unfortunately, one of the racers ignored the warnings and sailed on the original starting day. The yacht suffered considerable damage and one crew member was lost at sea in the storm. The satellite-based weather support was responsible for preventing considerable property damage and other loss of life in this particular sailboat race.

III. Summary

The use of operational environmental satellite data is well established in support of weather forecasting, especially severe storm forecasting and warning and large (global) scale forecasting. In addition, operational satellite data are used effectively in support of the following variety of activities:

- Ocean Current Navigation
- Ice Monitoring
- Citrus Industry
- Sugar Cane Industry
- Search and Rescue Operations
- Commercial Fishing Industry
- Agricultural Industry

Thus, operational environmental satellites have established their value and benefit to support many public warning functions and economic activities. To the tangible benefits must be added the intangible value of lives saved by improved natural disaster warnings to the public with respect to hurricanes, tornadoes, severe thunderstorms, and flooding. The advent of environmental satellites is the greatest significant advance in routine environmental monitoring that has been developed in history. The operational environmental satellite has earned its place as an irreplaceable weather and ocean observing tool in contributing towards the saving of lives and property from natural disasters and improving the efficiency of many sectors of our national economy.

The benefits discussed herein are evidence that the operational environmental satellite has earned its place as an irreplaceable weather and ocean observing tool. These satellites are making major contributions towards the saving of lives and property from natural disasters and improving the efficiency of many sectors of our national economy.

The Space Shuttle Focused-Technology Program: Lessons Learned

By PAUL E. FITZGERALD, JR.
Martin Marietta Denver Aerospace, Michoud Div.
and EDWARD A. GABRIS
NASA Office of Aeronautics and Space Technology

As the '60s drew to a close, and even before the flight of Apollo 11, the United States' first manned lunar landing, it became obvious relative to the future of our space programs, that

—1. The U.S. was in space to stay.

—2. The cost of expendable, single-use launch systems could not be sustained.

—3. Technology "existed" to develop a reusable Space Transportation System (STS) that could assure Item 1 and solve the problem posed by single-use systems in Item 2.

With respect to (1), U.S. determination to maintain technological leadership in the world assured the pressing of military, scientific, and commercial advantages of space. With respect to (2), extensive studies of potential space users underscored the wastefulness of expendable launch vehicles.

Regarding (3), most technology for most Shuttle subsystems did exist and had been demonstrated; however, for some systems we could claim *critical* technology only in concept and had not demonstrated it even in laboratory prototype.

In 1969, realizing this situation, NASA chartered the Space Shuttle Technology Steering Committee. It then defined, funded, and managed "focused" programs to demonstrate the utility and readiness of promising technologies. The NASA-led effort involved eight of its field centers and more than 100 industrial organizations. It produced many still valuable lessons. The following recalls the focused-technology program, its management structure, payoff in the Shuttle development, and lessons that may aid, for instance, space-station work.

What *is* a "focused" technology program? Depending on the industrial or governmental organization, the terms "research," "technology," "exploratory development," and "advanced development" would probably have slightly different definitions. These four terms represent a progression of technological development leading to the production phase of hardware and software.

We would also agree on at least two categories of research: "basic" research, the search for new knowledge, and "applied" research, which attempts to find new applications for existing knowledge. Our definition of "technology" involves the application of existing knowledge and thus excludes basic research tasks. For our purposes, we call the effort from 1969-73 in support of the Space Shuttle design simply "technology," recognizing it contained a percentage of all the classes of endeavor from applied research to advanced development.

Most of this "technology" effort resulted in breadboard, brassboard, and prototype hardware and software. *None of the technology funds was spent on production hardware or software actually intended to fly.* In this sense, Shuttle technology funds were used principally to demonstrate technology readiness.

To our definition of the term "technology" we add "focused," to mean work *in direct support of a planned program* (e.g., the Space Shuttle). The definition does not exclude the potential use of the technology in question on other programs, but does depend on the target program as its principal justification. Focused-technology projects usually demonstrate a capability, materials applications, or subsystem operational mode to fill a specific program need. A project may need to determine whether or not the program should be attempted with a given technology in its baseline configuration. Since this often involves funding more than one approach for the same design requirements, a focused-technology program inherently involves efforts which verify that certain advanced technology *should not be used* because of cost, technology, or scheduling risks.

Program Structure: One of NASA's great strengths—one not readily apparent in many government organizations—is its facility to respond rapidly to new program needs, opportunities, or problems with *agency-wide* organizational flexibility, cooperation, and sensitivity.

When the 1969 Space Task Group identified a reusable STS (compatible with the economics of space use in the 1980s and beyond) as a goal and determined that the technology "existed" to build it, there was a critical need to determine how much of that "existence" had to be demonstrated. In some cases, we also had to determine which of several dif-

Reproduced from Fitzgerald, Paul E., Jr. and Edward A. Gabris. The Space Shuttle focused-technology program: lessons learned. Astronautics and aeronautics, v. 21, Feb. 1983: 60-67, 72 with permission of the copyright holder Aerospace America.

ferent emerging technology options should be selected for application to the Shuttle. Major examples: the choice between metallic and non-metallic thermal protection systems, between the emerging aerospike engine design and the high-pressure bell-type engines, and among cost trades for numerous reusable Shuttle configurations. Some of these questions could be answered only by building hardware prototypes and testing them to ensure they could meet the requirements. The job of overseeing this work fell to the Space Shuttle Technology Steering Committee.

This Steering Committee was created by the NASA Administrator in 1969 with the appointment of a chairman from the Office of Aeronautics and Space Technology. The Steering Committee had no budget, no working staff, and if it had a written charter no one ever saw it. Yet, over the next four years, it was responsible for the expenditure of $146 million plus the tasks of nearly 3000 scientists, engineers, and technicians in government and industry. Within this four-year period, the Committee demonstrated critical technologies then candidates for the Space Shuttle baseline concept.

Seven working groups reported to the Space Shuttle Steering Committee: (F-1) Operations, Maintenance & Safety, Integrated Electronics, Structures and Materials, Propulsion, Aerothermodynamics and Configuration Verification, Dynamics and Aeroelasticity, and Biotechnology.

Each of these working groups was chaired by a middle manager from a NASA field center who was not only an expert in his field but also well enough known to be respected by his peers at other NASA centers. The membership of the working groups were selected from NASA field centers, USAF R&D laboratories, and the USAF Space and Missile Systems Organization. Each member was an expert in his technical discipline with sufficient insight into the abilities and interests of his center to know how its resources could best be used in technology-demonstration tasks. (All NASA centers were not represented on all working groups.)

LESSONS LEARNED

- **Government and industry must have clearly understood, well-defined roles.**
- **Industry must be a willing participant in the technology programs.**
- **There should be a free and rapid flow of information among government and industrial groups.**
- **Proper program start and stop criteria increase technology yield and decrease costs.**
- **The best expertise available, independent of the R&T or program interest of the organization, must be used.**
- **Program personnel must be active in the technology demonstrations for efficient technology transfer.**
- **Focused technology can have significantly higher yields than unfocused technology.**
- **Focused technology programs that are properly run are cost-effective.**

Each of these working groups convened several times a year to give the Steering Committee recommendations on—

—Technology tasks for the coming fiscal year—including scope, objectives, schedule justification, and priority rationale.

—NASA center best suited to manage each task.

—Funding.

The first factor required extensive study to determine which of the technology candidates required work before full-scale development. The second, which NASA center should be responsible for managing each task was, with few exceptions, deter-

T-1 FUNDING BY FISCAL YEAR AND TECHNICAL WORKING GROUP
Figures in millions of dollars.

Working group	FY70	FY71	FY72	FY73	Total
Operations, Maintenance and Safety	1	3	4	1	9
Integrated Electronics	7	9	6	4	26
Structures and Materials	11	22	17	3	53
Propulsion	5	8	7	1	21
Aerothermodynamics and Configuration	4	6	8	4	22
Dynamics and Aeroelasticity	1	3	5	2	11
Biotechnology	1	3	—	—	4
Total	30	54	47	15	146

mined by the working groups. Lastly, the funding estimates were made by the center responsible for the work; the resulting estimates generally proved to be dependable.

Since it had no staff or budget, the Committee and its chairman had to negotiate with existing "fund sources" for the use of *their* funds to do the necessary work. The three fund sources were the Office of Aeronautics and Space Technology (OAST), the Office of Manned Space Flight (OMSF) Advanced Development Office, and the OMSF Space Shuttle Office. The basic charters of these three NASA funding sources placed constraints on the use of congressionally-approved funds. The OAST divisions were committed to funding tasks toward the applied research end of the R&D spectrum; the OMSF Advanced Development Office lay in the middle of that spectrum; and the Shuttle Office leaned toward the developmental end. Within these constraints, the sources made the following allocations (millions of dollars):

Source	FY70	FY71	FY72	FY73	Total
OAST	21	35	31	12	99
OMSF/AD	7	8	6	3	24
OMSF/SSPO	2	11	10	0	23
Total	30	54	47	15	146

With no additional R&D budget allowance during the period 1969-73, NASA "focused" $146 million to ensure that the technology and the Space Shuttle would exist. Individual tasks which made up this focused effort fell into two broad categories:

1. Ongoing work directed specifically to a Shuttle application.

2. New work (not in the NASA R&D program), begun specifically for Shuttle application.

Ongoing work in 1969 (which did not have a critical Shuttle application) was often deferred so that the Shuttle-critical effort could be conducted.

An overview of funding allocations by technical working group, (T-1) gives insight into the weighting and spread of critical technologies by specific discipline.

The totals show that biotechnology was not a major technology concern; operations, maintenance and safety, and dynamics and aeroelasticity required more attention; integrated electronics, propulsion, and aerothermodynamics and configuration needed major resources; *structures and materials required more than a third of the total budget.*

This scaling of the criticality of technology into seven areas (based solely on dollars expended) reflects the relative magnitude of the problem in these areas. The issues associated with the Shuttle life-support systems and crew monitoring (addressed in the biotechnology area) were minor compared to reusable thermal protection, composite materials, thermal control and radiators, and composite payload-bay doors—all of which required significant advances in the state of the art.

Nearly 90% of the funds were spent in the first three years of the four-year program. This timing of expenditures will be commented on later.

Conduct of the Program: Several key facets of the technology program promoted success. First was the role of government vs. the role of industry. NASA's prime role in this program was to establish requirements for each discipline. These requirements were based on the central control which the government held in understanding the configuration as it evolved in Phase A and B studies conducted concurrently with the technology program. Various governmental organizations also played a central role by providing test facilities lacking in industry. This was particularly true for wind tunnels,

PAUL E. FITZGERALD JR., at left, serves as manager of advanced technology for the Michoud Div. of Martin Marietta Aerospace. He spent 20 years with NASA and DOD beginning in 1958 when he joined NASA-Langley as a wind tunnel test engineer. In 1962 he went to NASA-Johnson as project engineer on the first Little Joe II flight test vehicle and later on the Apollo Lunar Module ground-test vehicle certification. From 1969 to 1976 he managed the center's Advanced Development Program, which for four years focussed on Shuttle technology. He has also served in advanced R&T planning posts for the Naval Underwater System Center. **EDWARD A. GABRIS** manages the Transportation Systems Office in NASA's Office of Aeronautics and Space Technology. He has responsibility for technology for space transportation of the '90s and for chemical propulsion research and technology. Previously he managed work on technology development payloads for Shuttle and Spacelab. At NASA-Ames he managed a sound rocket program that launched almost 50 solar physics research payloads in four years.

arcjets, and propulsion test stands.

The contractor's role in the technology program was that of designer, manufacturer and tester of components, breadboards and brassboards according to government-supplied requirements. For this work approximately 80% of technology-development funds went to industry. In addition, industry liberally used its Independent Research & Development (IR&D) funds to augment the government R&T funding in those areas where industrial expertise was predominant.

This clear definition of roles for government and industry represents a primary reason for the success of the focused-technology program.

The willingness of industry to "play the technology game" was vital to the success of the program. Although industrial firms do not make substantial profits in such technology programs, they can gain leverage for winning subcontracts in a major program. Nearly all the eligible aerospace contractors were willing to bid to participate in the Space Shuttle focused-technology program. This allowed NASA to utilize the available wide resources of industrial expertise.

A third factor in success was the openness with which information was exchanged between the government and industry. The speed of this information flow was aided by the fact that none of the data was classified.

In summary, the following three factors proved the most important in executing the focused-technology program:

- Clearly defined and understood roles for government and industry.
- Willingness of industry to cooperate in the "technology game."
- Openness in the flow of information.

Technology Yield. How can the success of a large government/industry endeavor such as the Space Shuttle focused-technology program be judged? "Technology yield" offers a measure in terms of funds expended.

For the purpose of this discussion, we define "technology yield" as the percentage of program dollars spent for hardware, software, concepts, and operational procedures that found their way directly into the Shuttle baseline configuration.

The technology yield from each area may be summarized as follows:

Operations, maintenance, and safety. Although only modest sums went to this work (F-2), their effectiveness can be seen in the rapidly increasing percentage of applicable technology in 1972 and 1973. Major efforts in this discipline centered on lightning protection, definition of the launch processing system, and a reduction in the Shuttle turnaround time.

Integrated electronics. Some $26M was spent on integrated electronics (F-3). Major efforts included avionics systems architecture and development of a new software language, the Shuttle fuel cell, and numerous electronic components (including a high-density-data-storage tape recorder). The Houston Assembly Language (HAL) required more than four years to develop and cost more than $5 million. The new language is the standard today for STS and other space programs.

Structures and materials. More than a third of the total technology funding was spent in structures and materials (F-4). The particular efforts included the development of—

—Advanced carbon-carbon heat shielding for the nosecap and wing leading edges (where temperatures could reach 3000 F).

—Reusable surface insulation for the remainder of the vehicle (capable of withstanding 2200 F).

—Some advanced composite materials (primarily in the main-engine structural support, center-body struts, and payload-bay door.

—The Shuttle docking system.

The toughest task was the development of reusable surface insulation. Three contractors focused on this technology for more than five years and spent about $11 million on characterization of silica and mullite tiles. Development of silica tiles was the breakthrough that made the Shuttle reusable. This major development, begun as an industry IR&D program, was brought to fruition by the focused-technology program.

Propulsion. F-5 shows the technology yield for propulsion. Fiscal years 1970, 1971, and most of 1972 produced a very low yield. That happened because initially oxygen/hydrogen was baselined not only for the primary propulsion system (the Shuttle main engine) but also for the orbital maneuvering engines, reaction-control system, and auxiliary power unit. System tradeoffs (conducted the first two years of the program) proved this technology would be too complex, heavy, costly and unreliable to be used on the Orbiter. The final year of the Shuttle focused-technology program focused on storables and they proved 100% applicable. Thus, although the technology effort of the first two years did not come to fruition for design, the program nevertheless eventually produced the information needed for the baseline.

Aerothermodynamics and configuration. F-6 shows the funding distribution and percentage of applicable work developed in aerothermodynamics for the Shuttle baseline. Since the final configura-

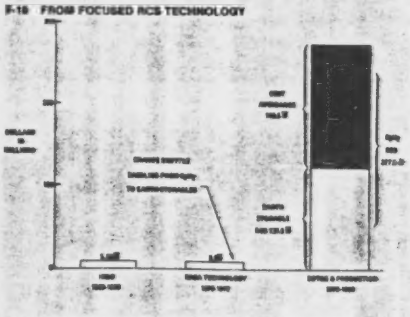
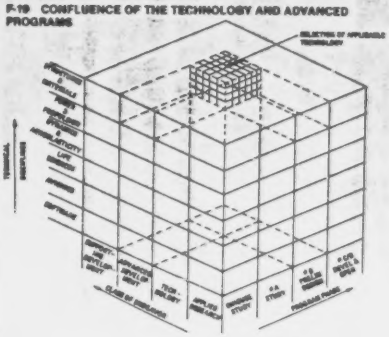
F-18 FROM FOCUSED RCS TECHNOLOGY



F-19 CONFLUENCE OF THE TECHNOLOGY AND ADVANCED PROGRAMS



tion was not selected until 1972, much of the "nonapplicable" work concerned configurations other than the one finally selected. Most of the funds for this category supported building and testing wind-tunnel models at various NASA and contractor facilities. This category also included important mathematical modeling and analytical-tool development aimed at reducing the number of wind-tunnel hours needed. Wind-tunnel testing spent on Shuttle aerodynamics totaled nearly 80,000 hr. Future programs will require significantly fewer hours due to the development of mathematical models and high-powered computers to solve complicated models within a reasonable time.

Dynamics and aeroelasticity. The technology program spurred much productive work in dynamics and aeroelasticity, both analytical and test-related. The NASTRAN program (developed for Apollo) was extended to several new areas and served well in analyzing structural dynamics of various Shuttle configurations. Most of this work was considered applicable to the Shuttle baseline (F-7).

Biotechnology. As can be seen from F-8, it was decided after two years that biotechnology issues (including life-support systems and food services) were well in hand for the Shuttle program and that no further technology funding would be required.

F-9, F-10, and F-11 depict the yield from the three fund sources: OAST, Shuttle Program Office, and OMSF Advanced Development. The results are obvious: funds for tasks toward the research end of the spectrum (generally OAST funds) were less effective than funds from the other two resources.

F-12 shows the total breakdown for FY70-73. It illustrates that more of the work became applicable as nonqualifying tasks dropped off toward the completion of the program.

Lessons Learned: Although often is may not be prudent to generalize results of a given effort, because of the pitfall of oversimplification, we believe it desirable to list lessons learned on this program to guide future, similar efforts.

The first three "lessons learned" we described under program conduct: clearly defined roles for government and industry; willingness of industry to participate in the technology program; and free and rapid flow of information among government organizations and industrial groups. To these we add the following inputs:

• Proper criteria needed for starting and stopping work. When designing a focused-technology program in support of a major flight program, there is a tendency to start too early and end too late. A degree of program definition must exist to focus technology projects. NASA's use of the phased development/procurement process for its major programs allows dovetailing technology projects having a degree of program definition.

The normal sequence of this process starts with a NASA in-house study designed to determine feasibility of a concept. This in-house study yields an initial conceptual design and an estimation of the types of system required in the first approximation of system sizing. It also provides the primary estimate of critical technology required. At this point the need for a focused-technology program can be addressed, but a program should not necessarily be started because technology issues will not necessarily be well defined.

Following the in-house study, contracted efforts are considered (such as Phase A studies) aimed at confirming in-house judged feasibility of the prospective space system. It is in this period that a focused technology program can be initiated since by their technology options and issues should be fairly well identified. It allows three to four years of technology effort before final technology selection (which generally occurs in the first two years of Phase C/D of the program). The cutoff point on technology must occur at this point because the prime contractor will have baselined it, in selection of subsystem contractors. F-13 shows an idealized focused-technology time-phasing chart.

• Proper split of effort between government R&T centers and government programs centers. The best expertise available should be used to address each technology issue without regard to the R&T or program interest of the government organization. There never was a clear dividing line in the Space Shuttle focused-technology program between the class of effort undertaken by NASA R&T centers and NASA program centers. Both were involved in some subsystem-level development as well as in basic technology work.

• Government in-house technology-transfer mechanisms. The question of technology transfer from personnel working on the technology program to personnel working on the major flight program is always a major concern. It is important to recognize that new technology will be used by personnel managing a major flight program only if they are thoroughly familiar with (and have firsthand knowledge of) the advantages and disadvantages of the new technology. *It is not sufficient to demonstrate the maturity of the new technology; it is equally important that the user be an active participant in the demonstration.*

The history of innovation is full of examples of the gap in time between demonstration of the maturity of a new technology and its first full-scale

(Continued on page 72)

Shuttle Focused Technology
(Continued from page 67)

application. This usually happens because the user community had not developed the technology and did not have confidence in it. This situation argues strongly for a "handover" of basic work (accomplished in an R&T center) to a program center where the effort continues into advanced development and demonstration. Other mechanisms of a technology transfer, such as symposia and good documentation of technology results, do not appear to have as significant an impact.

- Focused technology can have much higher yield than unfocused. In the mid-Sixties, the R&T manager of a major aerospace research laboratory ran a survey of some 500 tasks conducted in his laboratory over the previous ten years. He discovered that only three had progressed to the marketplace and only one of those three proved profitable—resulting in a yield of less than 2/10 of 1%. Too often companies and governments become involved in research for the sake of research alone. This tendency is eliminated by a focused-technology program which has an immediate end use if the technology is successful. Informal assessments of company IR&D programs indicate that this class of R&D generally yields less than 10%. In contrast, the Space Shuttle focused-technology program, spending $146 million over a four-year period, resulted in a yield of approximately 46%!

- Properly run focused-technology programs can save the real program substantial funds. During the Space Shuttle focused-technology program, numerous tradeoff studies guided the decision-making process and the choice of a given technology baseline. A number of these tradeoffs gave impetus to investment in one technology over another from a cost-savings point of view. F-14 through F-18 show some of the cost-avoidance values (in then-year dollars) which led to pursuing one type of technology over another (e.g. TPS, leading-edge TPS, fuel-cell, software, and RCS technology). As the figures indicate, many of the technologies funded by the government's focused-technology program had been preceded by industrial IR&D efforts.

Concluding Remarks: In the final analysis, the focusing of technology efforts on a given future program permits optimum confluence of program phase, R&T class of endeavor, and technical discipline (see F-19).

The government/industry team, which did such an outstanding job in demonstrating baseline technologies for the Space Shuttle, now stands on the threshold of adapting these, and many other, more-subtle "lessons learned," as it enters the era of the building of a space station and an American permanent presence in space.

Next Goal for Manned Space Flight?

By CLARKE COVINGTON and ROBERT O. PILAND
NASA Johnson Space Center

The various and flexible systems of this concept not only meet requirements of a wide range of roles and missions, but also permit imaginative organizational arrangements for evolutionary development

Reproduced from Covington, Clarke and Robert O. Piland. Space operations center: next goal for manned space flight? Astronautics & aeronautics, v. 18, Sept. 1980: 30-37 with permission of the copyright holder Aerospace America.

The Space Shuttle approaches its initial orbital flight test. Success will release a long-pent set of expectations for the U.S. manned space flight program. Future space activities will surely require expanded manned operations in space, and significant advances in space operations inherently require long gestation and development periods. Furthermore, developments in both technology and operational capability need a long-term goal to focus their activities to be most effective. Although it sometimes is not stated openly, there frankly is a need for a central, hard goal to maintain the dedication of participants in the space program and the interest and enthusiasm of young people in space technology to motivate their pursuing engineering and science careers.

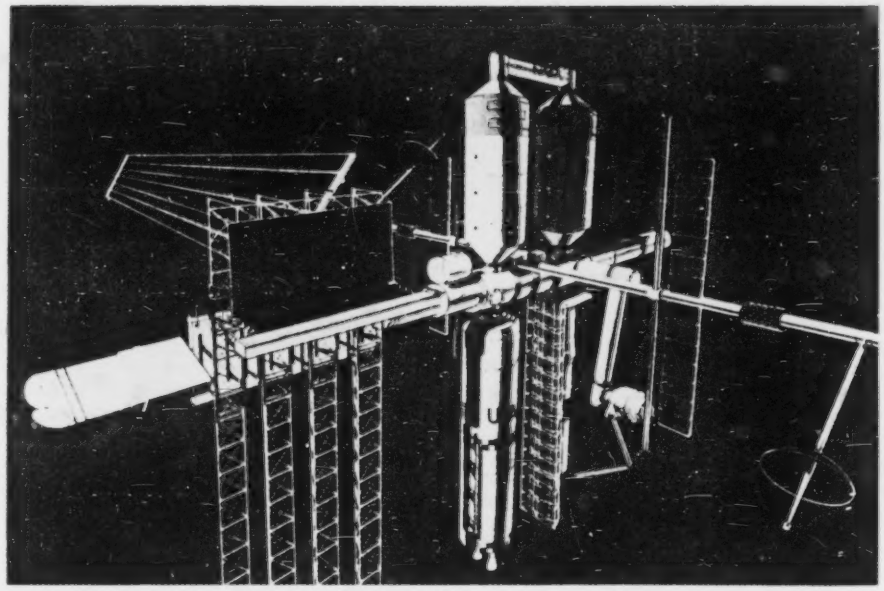
Although hundreds of proposals have been made for the next major space goal, including power satellites and space colonies, the strongest candidates for manned space flight can be grouped into the following five areas:

- Extensive Shuttle use.
- Permanent manned facility in low Earth orbit (LEO).
- Manned geosynchronous sortie mission.
- Permanent manned facility in geosynchronous orbit (GEO).
- Manned lunar sortie mission with or without a lunar base.

The first of these, exercise of Shuttle capabilities alone, is not an insignificant goal. The Shuttle should and will, hopefully, be exploited to the maximum. But Shuttle use, an evolutionary use, will neither require a new R&D thrust nor provide the clear focus needed for development of future technology and operations. A goal limited to Shuttle use only would represent a relatively slow pace of advancement.

On the other hand, a permanent manned GEO facility or a lunar base would bypass desirable, and perhaps necessary, evolutionary steps in technology and operational development, and both would require support that would probably exceed the scope of likely near-term funding.

The other two options, a manned LEO facility and a manned GEO sortie mission, both appear to have considerable value and represent reasonable technical and funding challenges. The operational deployment of a manned LEO facility would consolidate operations in near space, from the standpoint of both transportation and per-



The Space Operations Center (SOC) concept embraces operations as diverse as manufacturing large structures, tending free-fliers, and preparing and launching large spacecraft with propulsion units. At left here, beam-builder in action; at right, manipulator placing a spacecraft stage on strongback. Below center, two-stage manned orbital transfer vehicle (MOTV) at berth.

manency. Development of the means for manned GEO sortie missions would extend manned transportation from LEO, as provided by the Shuttle, to geosynchronous orbit. This capability would be an initial "LEO-GEO Shuttle."

In this article we describe recent thinking about a new concept for a Shuttle-serviced permanent manned LEO space station, a Space Operations Center. That name has been chosen to convey its mission-oriented role of construction, assembly, and servicing of space systems and spacecraft, and not just its being a site for conducting experiments and gathering scientific and applications data. We briefly review previous space-station concepts, compare future space goals, discuss objectives for a Space Operations Center, and describe the results of its initial analysis. NASA has no plans yet, we note, to implement such a concept. Currently planned studies simply explore the concept.

Space-Station Concepts: NASA has performed and sponsored studies of space stations off and on for many years. F-1 shows a 1967 concept that illustrates the thinking of the day. At that time many people thought artificial gravity would be required for long-term living in space, and the concept shown has a crew living area that rotates around a zero-*G* hub that houses inertially oriented experiments. The picture also shows the dependence of the station's configuration on its launch vehicle, Saturn V, as evidenced by its diameter and the use of a spent stage for a counterweight.

Apollo and then Skylab missions showed that a null-gravity environment contributes to fluid shifts, some cardiovascular deconditioning, loss of some bone calcium and muscle mass, and modest changes in the blood, but all these changes appear reversible. Such changes do not preclude longer exposure times than the 83-day Skylab mission, and no physiological changes uncovered suggest that a high level of human performance should not be expected in space.

Consequently, space-station studies shifted to zero-*G* concepts. Serious studies of a new logistics vehicle, which became the Shuttle, were under way, and space-station concepts soon evolved to the configuration shown in the 1970 illustration in F-2. It employs modules fitted inside the payload bay of the Shuttle concept of the day then assembled by manipulator into a space station.

(Meanwhile, the USSR was moving pragmatically ahead with their approach (F-3). Beginning in 1971 the Soviet Union launched the first of six 20-ton

38-036 O - 84 - 32

Salyut space stations. In 1979 Salyut-6 carried a two-man crew continuously for 175 days. The Salyut was visited periodically by manned Soyuz spacecraft and unmanned Progress vehicles each carrying 5000 lb of supplies. Both spacecraft can execute automatic, unmanned docking and can resupply propellants across the docking interface. A Soyuz always remains docked to the station for emergency return to Earth. The crew performed several operations, such as modular equipment replacement for station maintenance and attachment of a 10-m radiotelescope to the station's exterior. The station carried multispectral Earth-resource survey cameras, materials-processing furnaces, a liquid-helium-cooled infrared telescope, a gamma-ray telescope, a long-duration exposure platform, and medical equipment.)

Such NASA space-station studies had been largely applications- and experiment-oriented in their requirements. Consequently, the large "shopping lists" of possible experiments had a major influence on design requirements. Many of these ended up in conflict. Some experiments required one orientation, while others wanted another. Some required very low gravity, while others need some artificial gravity. There were also conflicts in altitude and inclination and other operational parameters. The resulting design concepts were complicated, and data handling and transmission requirements associated with the experiments were extremely high, as were estimated system costs.

But as the Shuttle moved along through development, concepts for long-duration experiments and applications began changing from "onboard," to "free-flying" with periodic servicing. In addition, ideas for advanced space systems predicted a need for large systems—of a size requiring construction in some fashion in space. It was this shift in thinking that paved the way for the Space Operations Center (SOC) concept.

Objectives of Permanent Manned LEO Facility: Assume with us that the next ten to twenty years will bring requirements for large, complex space systems and that geosynchronous orbit clearly becomes a primary operational arena. SOC then can be foreseen to have these chief objectives, which following paragraphs amplify—

—Construction, checkout, and transfer to operational orbit of large, complex space systems.

—On-orbit assembly, launch, recovery, and servicing of manned and unmanned spacecraft.

—Tending of co-orbiting free-flying satellites.

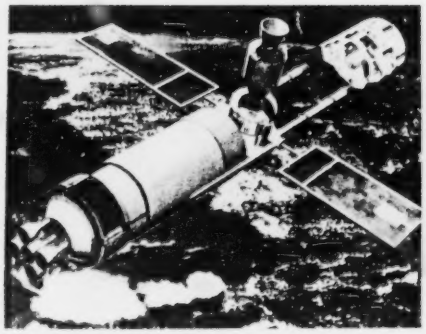
—Development of the capability for permanent manned operations in space with reduced dependence on Earth for control and resupply.

This list noticeably does not include on-board science and applications. Tended free-flying satellites would cover most such work. In fact, experiment and applications requirements will not be design drivers. SOC will be "optimized" to support *operations*. Experiments or applications that can tolerate SOC's operational parameters can be operated on board it, and, of course, an entire dedicated module can be attached to it at a berthing port.

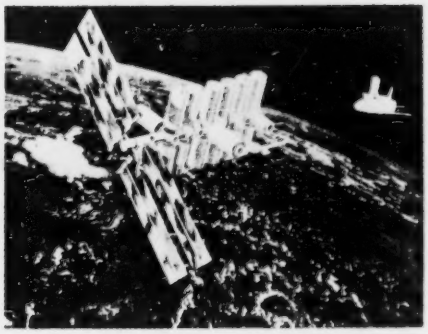
Space Construction: In the Eighties the Shuttle will be used in developing space construction methods and in constructing certain operational systems. However, current studies indicate that in several respects the Shuttle will not be able to handle directly the construction of some of the large and complex space systems under consideration. As shown in F-4, future systems could include large power modules with solar arrays in the 200-500 kw range, communications platforms with areas as large as 4000 m^2, and high-resolution parabolic antennas with diameter of 100 m or more. A permanent facility in space better suits conducting construction operations for such large structures and systems. SOC would support the flight development of the construction equipment and operational techniques begun with the Shuttle, and would then serve to construct, check out, and transfer to operational orbit such large systems.

On-Orbit Assembly, Launch, Recovery, and Servicing: Such work will require ability to fly manned and unmanned missions to GEO. A reusable manned orbit transfer vehicle (MOTV) will ultimately be required to perform the required

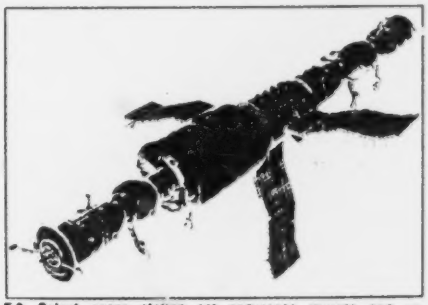
CLARKE COVINGTON, left, heads the System Design office responsible for conceptual design and system analysis of advanced space systems at JSC. He joined NASA in 1962. In the early '70s he was project engineer for the U.S.-USSR mission feasibility study and manager of design for the NASA Apollo-Soyuz docking module. For the past four years he has managed system definition within the JSC solar power satellite (SPS) concept-evaluation program. Covington holds an MSME from the Univ. of Texas. **ROBERT O. PILAND,** associate director for program development in JSC's Engineering and Development Directorate, has been involved in aeronautical and space R&D since joining NACA in 1947. For the past five years he has managed JSC's advanced programs, including its studies of the SPS and Space Operations Center. Before this assignment he served as director of JSC's Earth Resource Laboratory, manager of its Experiments Program Office, and deputy manager of the Apollo Spacecraft Program. A graduate of William and Mary, he also received a Master's degree in environmental management from the Univ. of Houston.



F-1 Concept for space station from 1967 reflecting the thinking of the day. Artificial gravity shapes design.



F-2 Configuration from 1970 featured Shuttle-delivered modules and assumed zero-*g* operations.

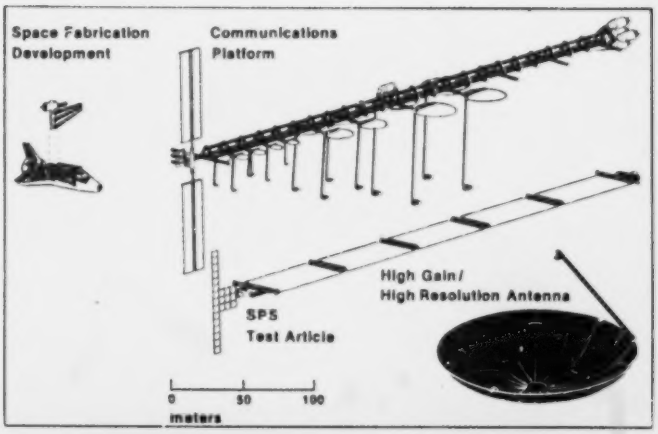


F-3 Salyut space station set endurance records and underscored combined orbital operations.

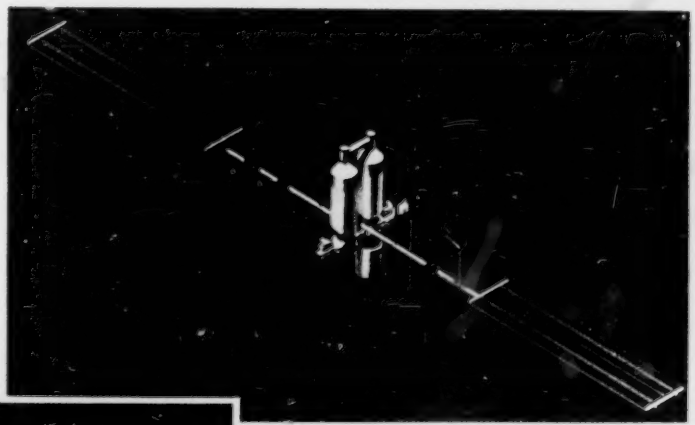
services. A single Shuttle mission can deliver a 5000-lb payload to GEO using an inertial upper stage. The assembly of two or more stages together in orbit to form a multistage vehicle too heavy for a single Shuttle launch opens up the possibility of large payloads to GEO and higher-energy, deep-space missions. Studies have shown the feasibility of assembling separately launched stages using the Orbiter as an assembly base, but the operational aspects appear formidable. By comparison, the on-orbit basing of a staged assembly allows not only operational advantages, but also offers the economy of recovery and space servicing of reusable stages for both unmanned vehicles and MOTVs. In addition, a permanent facility in orbit, with proper orbital phasing, can recover a payload returned from a planet and quarantine it before risking delivery to Earth.

Tending Free-Flying Satellites: For best results some space operations, such as construction, will require crew participation almost continuously. Others, such as routine data collection, can be done satisfactorily without crew intervention. And some operations actually proceed best without the disturbance of human presence, although perhaps requiring periodic servicing, adjustment, fault detection, and repair managed better by a human than a robot. Such operations include materials processing, which requires extended periods of extremely low acceleration, and a large space telescope, which can be contaminated by nearby crews, but may need frequent film and instrument replacement, calibration, etc. The SOC concept operates satellites of this kind in a co-orbiting mode at whatever separation distance may be required, with recall command, rendezvous, and berthing to the Center for servicing when necessary. Tending co-orbiting satellites is similar in equipment and operations to supporting an orbit-transfer vehicle (including means to berth payloads the size of the Orbiter bay, access to the interior and exterior of the serviced vehicle, rendezvous and berthing remotely controlled from the SOC, and servicing and repair facilities.)

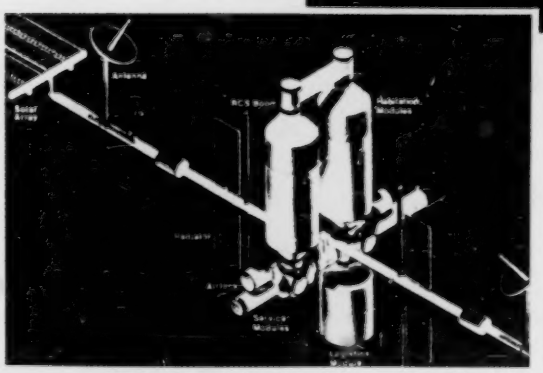
Space Operations with Reduced Dependence on Earth: SOC should move toward permanent manned operations in space without frequent resort to Earth for resupply and day-to-day control of operations. Reducing dependence on supplies from Earth significantly alters design requirements for electrical power generation and storage, recycling atmosphere and water, on-board health maintenance (which provides inherent clinical physiological data accumulation), and comprehensive emergency considerations (which in turn involves a high degree of redundancy both in systems and living quarters). The present mission management and control process is characterized by people-intensive ground monitoring and control involving large supporting facilities and highly integrated ground- and flight-crew operations. To reduce dependence on



F-4 The typical space construction projects under study, treating very large structures, some with large power modules, lend themselves to SOC operations.



F-5 Rudimentary Space Operations Center would be able to sustain crew and operations for ninety days without assistance—without presence of a Shuttle.



F-6 Pair of identical service modules form the central spine of SOC. They offer several docking and berthing ports for the Orbiter and modules.

Earth monitoring and control, SOC would have to provide for increased systems monitoring, fault isolation and failure analysis, and storage and callup of extensive sets of data for on-board control of the stations and missions.

SOC "Core" Elements: The Space Operations Center would be a self-contained facility built up of several Shuttle-launched modules. With resupply, on-orbit refurbishment, and orbit maintenance, it would operate continuously for an indefinite period. It would usually be manned, but it could be operated automatically.

Safety of both the SOC and its crew would be a major design consideration. Through subsystem and module redundancy SOC could sustain itself and its crew for ninety days without assistance in

the event of a major failure, including the functional loss of an entire module.

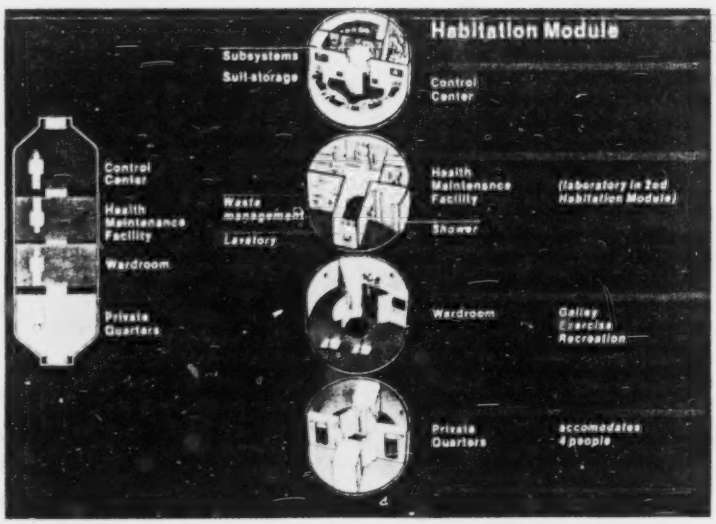
F-5 shows the arrangement of SOC core elements. Two identical service module halves form a central spine having several docking/berthing ports for other modules and the Orbiter. Each service module provides electrical power, generated by two large solar arrays on long booms; guidance, control and stabilization; reaction control; communications; and airlocks for EVA. These independent but interconnected sections give the necessary redundancy of critical systems.

Two habitation modules are berthed to the service module. Each contains a command center capable of controlling the entire SOC, private quarters for a crew of four, food-preparation, hygiene, and waste-management facilities, and exercise and recreation equipment. In addition, one module has a health-maintenance facility, and the in it will help develop a better understanding of the physiology of living and working in space.

The two habitation modules are joined at the "top" by a tunnel. This gives each two exits in an emergency. The tunnel also contains Shuttle docking ports alternative to the primary docking position at the end of the service module.

A logistics module, normally berthed to the service module, stores consumables and spare parts. The Shuttle would replace it during resupply visits, thus avoiding large-scale transfer of cargo. The service and habitation modules would always carry emergency stores to hedge against loss of access to the logistics module.

Our initial studies have in good measure assumed available subsystem technology. SOC subsystems draw heavily on Skylab, Shuttle, and Power Extension Package hardware. New subsystems can be added or tested as they become available.



F-6 Typical layout of a habitation module. Much study remains to be done before choosing a firm design.

other module a small laboratory. The arrangement of space within the habitation modules will be governed by various factors that have not yet been adequately defined. F-6 illustrates a plausible layout, but not necessarily the best one.

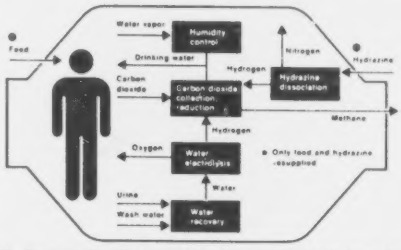
The health-maintenance facility is more than a conventional clinic. It primarily serves to treat minor illnesses and injuries—including making X-rays and conducting minor surgical procedures—but, in addition, it provides extensive monitoring of crew health and body functions. Data obtained

An exception to this approach was the environmental control and life support system (ECLSS). In most previous programs (except Skylab) fuel cells have provided both electrical power and water. Since the SOC uses solar cells for power, water must be either resupplied or reclaimed. Reclamation of both water and oxygen was selected to avoid very large resupply requirements. F-7 shows a simplified schematic of the system chosen. The only resupplied consumables are food and hydrazine, the latter being dissociated to make up both atmo-

spheric nitrogen leakage and the hydrogen requirement of the Sabatier reactor that reduces the carbon dioxide exhaled by the crew. Hydrazine is also used as a monopropellant in the reaction-control system to simplify resupply requirements.

The regenerative ECLSS has been the subject of an extensive development effort for several years, including over 1700 hr of tests on a first-generation system and several second-generation subsystems. The remaining second-generation hardware should be delivered and prototype testing of an integrated system should be completed before the end of this year. Plans include modifying the system as necessary and making manned system tests in a 20-ft vacuum chamber.

The communications and tracking system also represent a significant performance increase over previous space systems, primarily in the number and diversity of communications links (F-8). Hardware requirements can be satisfied by Orbiter-type equipment in most cases.



F-7 **Regenerative life-support system** has this basic form. The only resupplied consumables are food and hydrazine.

SOC Operations Elements: Besides service, habitation and logistics modules, the SOC concept embraces construction and flight-support facilities (F-9). A control cab and Shuttle-type manipulator on a movable boom serve both.

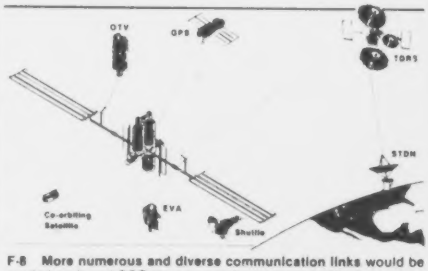
The construction facility would fabricate and assemble large structures; install, integrate and check out subsystems, and separate and launch a completed system to its operational orbit.

The principal elements of the facility are construction equipment and a holding fixture. The beam builder is one type of construction equipment. From flat stock it makes triangular-truss beams in any desired length. The fixture holds the beams correctly and positions the beam builder to produce additional beams in the locations desired. The holding fixture also moves the structure lengthwise to allow attachment of secondary structure and subsystems at a fixed worksite. Since its design depends on the article being constructed, the fixture must be replaced or reconfigured for each different structure.

A manipulator and tools associated with the holding fixture aid the installation of subsystems. The opening illustration shows a solar-cell blanket being dispensed from a container attached to the holding fixture. EVA will often be required to provide the needed dexterity; most operations will not repeated enough for automation.

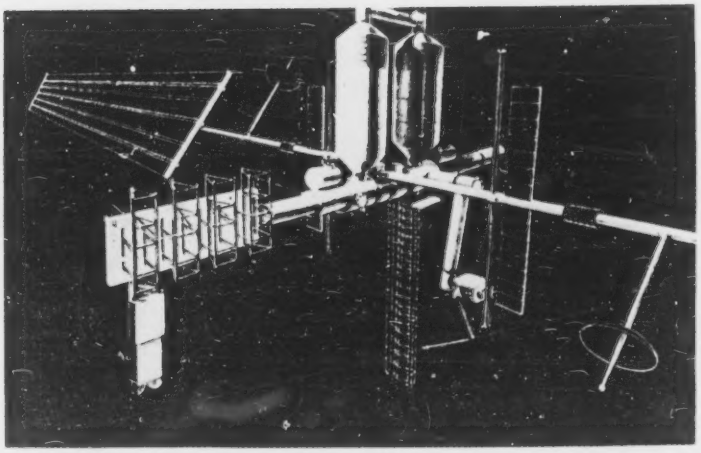
The flight support facility serves to assemble, check out, and launch multistage solid-rocket vehicles; assemble, check out, fuel, launch, and recover the MOTV, and recover and service co-orbiters.

A strongback berthed to one of the service-module ports (opening illustration) forms the main member of the assembly unit for solid-rocket stages. As stages and payloads are delivered by the Shuttle, they are placed on the strongback by the SOC manipulator. When all stages have been delivered, mechanisms on the strongback mate the stages and payload to complete the assembly. The vehicle is then checked out. For launch, a tilt table rotates the vehicle away from the strongback and separates it from the SOC. The vehicle then moves to a safe distance before final orientation and ignition.



F-8 **More numerous and diverse communication links** would be carried on board SOC than on previous space systems.

The MOTV, a two-stage reusable manned vehicle for GEO sortie missions, parks at a lower docking port of one of the service modules (opening illustration). Before launch, it is fueled from the Shuttle (or from storage tanks on the SOC), using propellant-transfer equipment on the SOC. For launch, the MOTV separates from the docking port and moves to a safe distance from the SOC before engine ignition. The first stage returns to the SOC before the second stage and is stored temporarily on the stage-assembly strongback. After completion of a mission, the second stage with crew module returns to the SOC and either docks or is berthed by the manipulator to its port on the service module. The first



F-9 SOC features construction and flight-support facilities, in the general scheme illustrated here. Note beam builder at left and manipulator on strongback at right. The opening illustration of the article shows more details, notably of rocket-stage assembly.

stage is mated to the second using the manipulator, and the vehicle is then checked out in preparation for the next mission.

The same units service co-orbiting satellites. Either the MOTV or the Shuttle docking port can dock a satellite to allow pressurized access to its interior.

Concluding Remarks: SOC requires additional exploration both in terms of its operational values and its design. In particular, its justification depends on the actual "demand" for large space systems. And even if requirements for large systems materialize, they must be shown to exceed the capability of the Shuttle, thereby necessitating a SOC-like facility.

The SOC concept covers assembly, launch, and recovery of space vehicles. Mission analyses are required to determine under what conditions such assembly in space will be effective and for what types of systems.

SOC would service co-orbiting automated satellites. Many satellites requiring servicing will not be in the orbit of the SOC, and it is likely that they will be most effectively serviced by the Shuttle. But certain types of satellites, not sensitive to orbital requirements, should benefit from frequent servicing and manned interaction with a SOC-like facility.

The system technology that should be incorporated in the SOC represents a considerable challenge of *decision*. In the past, performance based on weight requirements required the selection of the most advanced technologies available. The SOC presents a somewhat mixed situation. In certain areas, existing technology is adequate. On the other hand, it may be necessary to develop new criteria for deciding between an existing and a more advanced technology. The demonstration and use of advanced technology may be a reasonable objective itself.

Without question SOC will necessitate advancing the state of the art in many areas. Variable-geometry structure and controls interaction, software planning and management, construction and vehicle assembly, and servicing represent challenges.

Integrating systems to gain performance advantages requires careful consideration in the SOC concept. There are obvious opportunities to integrate, in various ways, the life-support system, fuel cells, electrolysis units, and propulsion system, making them interdependent. The analyst would certainly be able to show performance gains from such interrelationships. The system developer and the operators, however, might prefer to maximize the independence or modularity of these systems.

The SOC offers important options from the standpoint of program development. Its necessary elements lend themselves to a variety of organizational arrangements for development, including multi-center, multi-company, and multi-national participation. Obviously these options need to be considered from many standpoints.

The SOC concept also lends itself to evolutionary development. It would be very desirable if the various elements of the SOC could be developed somewhat independently and tested with the Shuttle, serving useful purposes as independent operational elements before being integrated into the whole SOC system. An obvious example: a power module designed for use as the service module of the SOC as well as for automated platforms. In short, the concept offers room for imagination and ingenuity in planning an evolutionary development.

We believe the aerospace community should now begin to weigh the next goal for manned space flight. The SOC preliminary study we hope will stimulate and encourage discussion—help guide both further studies and technological developments. ■

AN AIAA LIQUID PROPULSION TECHNICAL COMMITTEE ASSESSMENT

Liquid-Rocket Propulsion Technology

Edited by Robert L. Sackheim, Committee Chairman.

The federal government should reinstate and firmly commit a long-range integrated program to develop liquid-rocket technology for the coming generation of space systems

Reproduced from Liquid-rocket propulsion technology. Edited by Sackheim, Robert L. Astronautics & aeronautics, v. 21, Ap. 1983: 46-52 with permission of the copyright holder Aerospace America.

Space systems have become a major factor in our daily lives. We depend upon our national space assets for communications, weather forecasts, military defense, terrestrial resource management, navigation, and the generation of new and vital scientific data for all mankind, to name only the most notable. All depend directly on space transportation and therefore on the high-performance rockets that power our vehicles. Transportation propulsion systems define the limits of size, mass, cost-effectiveness, and availability of all space systems. The propulsion system represents upwards of 85% of the mass of any space system going into orbit. As we look to future systems, we find that our vehicles must have better propulsion, particularly better liquid rockets, to power them. This assessment explains why. It defines our many liquid-rocket needs. They need and deserve support—funds, manpower, and development planning.

A marked slowdown in rocket technology occurred after the successful Apollo manned lunar landing in 1969. Although the pace quickened somewhat with the advent of the Space Shuttle program in 1972, it never recovered the original zest of the late 1950s and 1960s. The Space Shuttle's systems represent a state-of-the-art landmark.

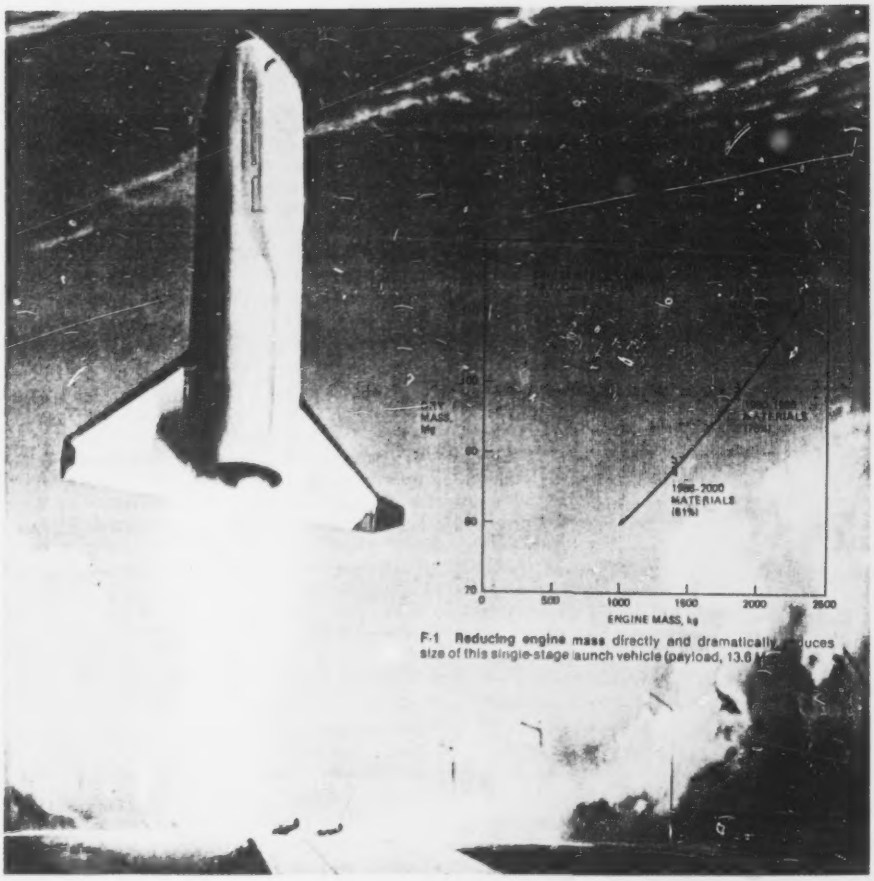
Today, most problems of the older liquid-rocket propulsion systems are under reasonable control, as attested to by the very low failure rates of the past decade compared with the 40% failure rate of the '50s and the 10-20% failure rates of the '60s. Propellant combinations, moreover, appear to have become standardized (e.g., liquid oxygen (LOX)/hydrocarbon; LOX/hydrogen; nitrogen tetroxide (NTO)/hydrazine compounds). Higher-energy propellants, such as fluorine, may enter the picture, but as yet missions do not justify their use.

From 1962 to 1982 upper-stage engines were developed with little, if any, difference in technology from generation to generation, largely the combined effect of very limited funding for liquid-rocket technology after the mid-Sixties and lack of clearly defined space goals. For example, Apollo, Transtage, Lunar Module, Shuttle OMS, and MX engines have strong similarities in concept and technology. The strong technical advancement represented by the Space Shuttle Main Engine (SSME)—with its high chamber pressure, staged combustion, and high-power density pumps—has become a rarity, if not a singularity, in liquid-rocket technology.

Needs and Benefits: We must have advances in four basic types of liquid-rocket technology to improve our ability to operate in space:

- In launch-vehicle technology, to enable a ma-

Copyright © 1983 by the American Institute of Aeronautics and Astronautics



F-1 Reducing engine mass directly and dramatically reduces size of this single-stage launch vehicle (payload, 13.6 M[illegible]

jor expansion in space utilization and dramatically reduce the overall cost of space operations. A growth version of the Shuttle could increase payload delivery to low Earth orbit (LEO) from 65,000 to over 100,000 lb.

- In high-performance systems for orbital transfer, to gain mission flexibility and minimize costs in terms of spacecraft size.
- In high-performance space-storable propulsion, to upgrade planetary spacecraft and make possible efficient maneuverable spacecraft.
- In high-performance auxiliary propulsion, to increase payloads and extend orbit stationkeeping and attitude control.

All these advances must be accompanied by new or improved systems for long-term fluid storage and resupply in space. Taken together, these developments would enable important new missions to be performed and would lower cost and improve effectiveness of all U.S. space activities.

Moreover, military space missions impose different propulsion requirements in each of the above key technology areas. Military launch-vehicle technology will tend to be driven by fast response, quick turnaround, survivability, launch environment (both peace and war), and military threat.

Similarly, military OTV (orbital transfer vehicle) and on-orbit propulsion will be driven by different requirements—acceleration control, long storability and long dormancy, low observables, survivability, active defense, and minimum contamination.

As yet the U.S. has no means for high-performance, quick-turnaround launches. Projected requirements for total impulse, low contamination, and survivability cannot be met by the state of the art in OTV and satellite propulsion technology.

Much emphasis has been placed on lowering the cost per pound of payload into orbit from the current $25,000 per pound into GEO and the anticipated $16,000 per pound for the Shuttle/inertial upper stage (IUS) to about $6,000 per pound for advanced Shuttle upper stages. The following sections

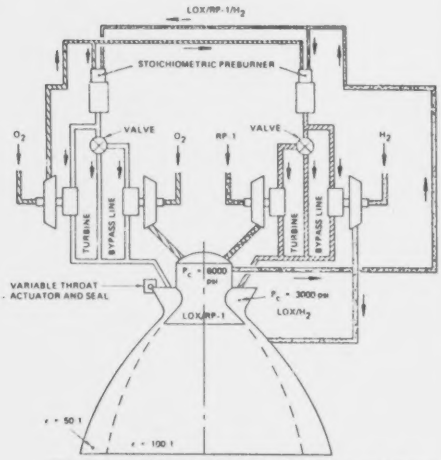
address the systems and technology needed to attain these objectives.

Transportation to LEO: Improvements will be required in the liquid-rocket engines used for LEO transportation. These improvements concern both the SSME and future engines utilizing LOX with either H_2 or hydrocarbon (HC) or both as the fuel. Salient points concern engine operating costs, engine mass, and altitude compensation.

Operating costs will drive design for all reusable hardware having higher launch frequencies than the Space Shuttle. One study indicates that $1.7 billion could be saved over the life of advanced vehicles by developing an extended-life SSME for an R&D cost of $247 million. Another study has shown that maintenance costs of liquid-rocket engines can be reduced by developing monitors to detect rate of component wear or impending failure. They would also support crew safety during flight.

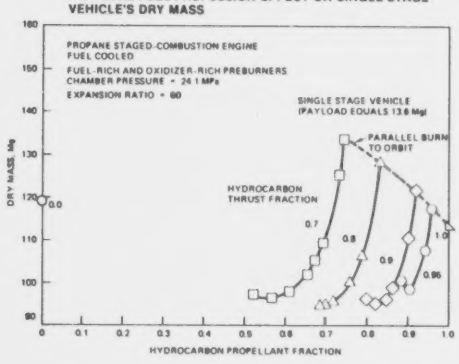
The mass of liquid-rocket engines greatly influences design options for advanced launch vehicles. An engine mass reduction of 50% in the single-stage concept shown in F-1 can bring the vehicle dry mass down more than 25%. Engine mass reduction also shifts forward the vehicle's center of gravity (CG). That lessens loads on aerodynamic surfaces and control systems, producing a further reduction in vehicle dry mass (making, for instance, the curve shown in F-1 conservative). Research in progress is directed at reducing the mass of vehicle structure, but little has been done recently to reduce the mass of liquid-rocket engines. In the near term, substituting advanced composites for more conventional materials might reduce engine mass 24%. By century's end, advanced engine designs could reduce mass over 35%. This R&D effort should be vigorously pursued.

By their nature, Earth-to-orbit vehicles fly throughout the entire range of atmospheric pressures from sea level to vacuum. Engine (nozzle) characteristics that work well at low altitudes suffer in vacuum and vice versa. The rocket-engine designer deals with atmospheric variability with several techniques, a notable one being to maximize the combustion-chamber pressure. The SSME has a higher chamber pressure than previous engines, and future engines may operate at even greater pres-

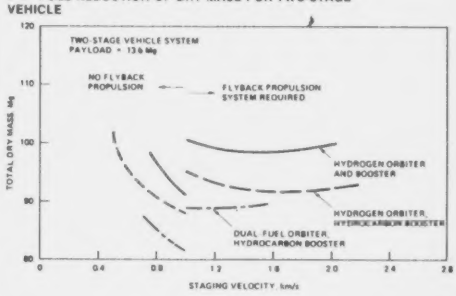


F-2 Dual-expander engine using LOX/RP-1/LH_2 offers high performance but remains largely undeveloped and unexploited.

F-3 DUAL-FUEL-PROPULSION EFFECT ON SINGLE-STAGE VEHICLE'S DRY MASS



F-4 FUEL REDUCTION OF DRY MASS FOR TWO-STAGE VEHICLE



sures. Higher pressures will probably require advanced cycles; and even at that, one study of technology improvements that would allow higher chamber pressures did not find the expected vehicle improvement. Gas-generator losses increase with chamber pressure. For staged-combustion cycles, pump-discharge pressure, turbine-inlet temperature, and cooling requirements increase with chamber pressure. The designer has at least one unexploited way out of this bind. An advanced cycle with two combustion chambers at different pressures may allow an increase in pressure in the higher-pressure chamber by using power from the fluids of the lower-pressure chamber. The so-called dual-expander engine uses this scheme (F-2).

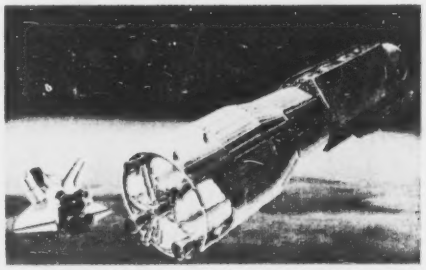
After optimizing combustion-chamber pressure, the designer may elect to see what improvements can be obtained from an extendable nozzle. Many concepts have been proposed, from translating cones to folding petals. Some are usable at low altitude in the stowed position, and some require the nozzle to be extended at ignition. An aerospike nozzle, with its free boundary, allows the nozzle effective exit-area to vary ideally with atmospheric pressure. Unfortunately, the combustion chambers for such concepts must be spread around the nozzle perimeter, which results in additional throat length and more cooling requirements. Vehicle-integrated nozzles should be considered, as Rudi Beichel proposed in his June 1975 *A/A* article. Flaps above and below the engines can vary expansion, or nozzles with circular throats around a vehicle surface can give an aerospike effect.

Changing the effective throat area of the nozzle, rather than the exit area, can also provide altitude compensation. The dual-expander and dual-throat and split-combustor aerospike engines use this approach by shutting off several of the combustion chambers, and letting the remainder use the entire exit area. The fact that this tactic reduces thrust at higher altitudes does not present a problem, since it is necessary to limit vehicle acceleration anyway.

Altitude compensation must be addressed before advanced vehicles can be developed. Both engine and vehicle studies are needed to compare the relative merits of the options. In some cases, experimental testing will be required.

High-Pressure Engines: Future Earth-to-orbit vehicles may well use hydrocarbon fuels in high-pressure engines, rather than hydrogen, or possibly tripropellant engines, which take advantage of the favorable characteristics of hydrogen to improve an engine that gets most of its thrust from hydrocarbon. The engines being considered have combustion-chamber pressures about equal to that of the SSME (3,000 psia).

From the vehicle standpoint, hydrocarbon fuel provides two main advantages over hydrogen: greater density, allowing the vehicle to be smaller and lighter, with smaller engine components, and requiring less pump horsepower for a given thrust; and less pressure loss, because the denser fuel increases thrust per unit throat area. Several studies have shown the value of hydrocarbon propulsion for advanced Earth-to-orbit vehicles, particularly for a recoverable liquid-rocket-booster derivative (replacing the current solid-rocket boosters) of the Space Shuttle. Life-cycle costs for the liquid-rocket boosters would be nearly twice as high with hydrogen as with hydrocarbon fuel, per recent study.

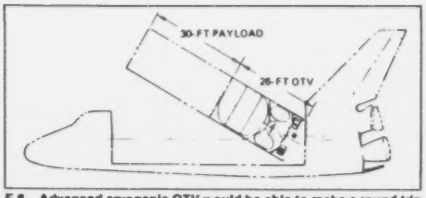


F-5 **Advanced storable-propellant stage** for placing 12,000-lb payload in GEO requires several key technology advances, such as development of small high-speed turbopumps.

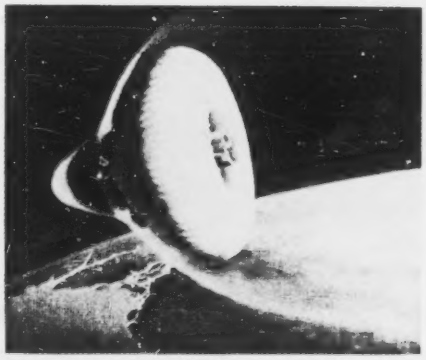
On the other hand, hydrogen provides higher specific impulse. Combining high-density and high-specific-impulse fuels can yield a more efficient vehicle than with either fuel alone, as Robert Salkeld has shown in his March 1974 *A/A* article.

Completely new Earth-to-orbit vehicles will be developed some time in the distant future. When these advanced vehicles will be required will depend upon many factors (e.g., traffic growth and the development of a liquid-booster Space Shuttle derivative). Prospective development of these vehicles should influence today's rocket-engine research.

Two concepts currently favored would benefit from advanced hydrocarbon engines. The first, a single-stage, vertical-takeoff vehicle could deliver a payload similar to, or somewhat smaller, than that of the Space Shuttle. F-3 shows that an optimum dual-fuel vehicle would have a dry mass of 94,000 kg. The vehicle using only hydrogen fuel, shown at a hydrocarbon propellant fraction of zero, would have a dry mass of 119,000 kg—over 25% greater. The second concept, a two-stage parallel-burn vehicle, likewise has more dry mass (about 12% more)



F-6 Advanced cryogenic OTV would be able to make a round trip to GEO with 16,000-lb expendable or 5000-lb reusable payload.



F-7 Concept of aerobraked OTV using an inflatable "ballute" would require engine throttling from full thrust down to 5%—a major R&D challenge.

using just hydrogen fuel than the minimum obtainable with hydrocarbon propulsion (F-4).

Based on the vehicle results just discussed, future efforts should include high-pressure hydrocarbon fuel engine research. Of particular interest are preburners and gas generators with hydrocarbon fuel (both oxygen-rich and fuel-rich). Cooling with both hydrocarbon fuel and oxygen needs to be considered. Studies should complete the data base for various cycles. Actually, a whole family of engines with two combustion chambers at different pressure should be considered.

Unquestionably, advances in liquid propulsion can improve future Earth-to-orbit vehicles. For advances to be ready when needed, however, R&D should be backed *now* with more money in a well-defined and consistent program.

Orbit-Transfer Vehicles (OTVs): Many future missions will require advanced OTVs. Spacecraft to be transferred from LEO to GEO will go up in size from the current 5,000 lb to more than 10,000 lb by the late '80s. For the '90s, missions with round-trip capability both to service satellites at GEO and for manned sorties call for vehicles weighing up to 25,000 lb.

Recovering the OTV may be cost-effective for some missions and is mandatory on manned sorties. Reusability also requires rapid turnaround techniques, probably based on design forethought and

F-8 ALTERNATIVE CRYOGENIC OTV CONCEPTS

	LOW THRUST	AFT CARGO COMPART	SPACE BASED
PURPOSES/ BENEFIT	• GENTLE ACCELERATION FOR LARGE SPACE SYSTEM • LARGER SPACECRAFT, FIX IN LEO	• MINIMIZES ORBITER-OTV INTERFACES • MORE PAYLOAD SPACE AVAILABLE	• ELIMINATE TRANSPORTATION OF OTV TO AND FROM ORBIT • MORE EFFICIENT TRANSPORTATION
UNCERTAINTY	• TOROIDAL LIQUID OXYGEN TANK • SMALL HYDROGEN/ OXYGEN PUMP-FED ENGINE	• SEVERE THERMAL/ACOUSTIC ENVIRONMENT • IN-FLIGHT ASSEMBLY TO SPACECRAFT	• SPACE MAINTENANCE • EXTENDED SPACE EXPOSURE
FUTURE	• LSS ARE "NEXT GENERATION." • COMBINE FEATURES IN BASIC OTV	• NEEDS FURTHER CONCEPTUAL STUDY	• NEXT GENERATION; INTEGRATE TRANSPORTATION WITH SOC STUDIES

automated monitoring of component "health." Ideally, a reusable OTV should be designed for man-rating from inception, allowing for increased margins of safety, built-in backups, and alternate modes of safe operation.

As NASA proceeds with its next probable major initiative—permanent occupancy of a space station in LEO—space-based rather than ground-based OTVs will evolve. Space-basing will evoke new design and maintenance concepts.

Two propellant combinations are of interest for future OTVs: Earth-storable nitrogen tetroxide/monomethylhydrazine (NTO/MMH) and cryogenic LOX/hydrogen. The latter offers higher performance but is limited to missions of only a few days' duration because of propellant boiloff. NTO/MMH better suits missions requiring space residence for months or years. Advanced Earth-storable-propellant OTVs are of particular interest to the USAF. They should achieve operational status in the late '80s; advanced cryogenic OTVs are not expected to become operational until the mid-'90s.

Both NASA and the USAF are investigating storable-propellant stages employing NTO/MMH. Although toxic and corrosive and lower in specific impulse than cryogenic oxygen and hydrogen, these propellants have two important advantages. They are denser, thus allowing for a more compact stage, and they do not require a complex and costly thermal-control subsystem. Since there are no propellant boil-off losses, a storable-propellant stage is attractive for missions that require long-term orbit maneuvering. This storable propulsion technology suits a number of vehicles, including a small, quick-reaction transfer stage that could be used with such new launch vehicle concepts as the "Advanced Military Spaceflight Capability (AMSC)."

An advanced pump-fed storable stage (F-5) could place a 12,000-lb payload into GEO. This stage would employ four pump-fed engines providing 3750 lbf each, yielding a high specific impulse by operating at a chamber pressure of 1,400 psi with a nozzle area ratio of 400:1. The 340-sec I_{sp} would be about 10% higher than the yield of today's pressure-fed storable bipropellant engines. The 6,000-lbf Shuttle pressure-fed OMS engine delivers an I_{sp} of only 313 sec due to its low chamber pressure of 125 psi and nozzle area ratio of only 55:1.

The high-density I_{sp} associated with the pump-fed storable stage permits a more compact propulsion system (8.5 ft long) and therefore longer payloads in the Shuttle cargo bay than can be achieved with a cryogenic stage. But it cannot be brought into being without several key advancements: high-chamber-pressure NTO regeneratively cooled thrust chambers, small high-speed turbopumps (gas-generator cycle), low-cost light tankage and propellant-acquisition systems, a low-cost reliable tank pressurization system, and high propellant-mass-fraction stage. The USAF will be pursuing these technology developments over the next several years. The sooner this work can be accomplished, the better for advanced system development.

T-1 CRYOGENIC LIQUID PROPULSION ADVANCES NEEDED FOR OTVS

Advances	Impact	Benefit
A. Main engine		
Increased I_{sp}	High pressure, more expansion	100 lb payload per 1 sec I_{sp}
Low-thrust concepts	Pumps, injectors, heat exchanger	Propellant settling, or low acceleration
Light weight	Use of composite materials	1 lb payload per 1 lb engine weight
Reusability	Monitoring and checkout equipment	Saves operating costs on some missions
Man-rating	Reduced stress; redundancy	Required for manned sortie
B. Propellant supply		
Reusability	Propellant tanks checkout	Save operating costs
Reduced vehicle length	Torus tank (dynamics)	Key to accommodate long payload
Zero-gravity propellant management and transfer	Acquisition, mixing, venting, insulation and heat exchangers	Enable mission versatility and resupply on orbit
Increased storability	Reduce cryogenic boiloff	Increase space residence

Unlike the storables, cryogenic propellants—liquid oxygen and hydrogen—are nontoxic, noncorrosive, and up to 50% higher in performance. (A 1 sec gain in I_{sp} is worth about 100 lb of payload on round-trip missions from LEO to GEO).

The Space Shuttle Centaur under development represents the state of the art in high-energy upper stages. It can deliver 14,000 lb to GEO, using some 46,000 lb of H_2 and O_2 at an I_{sp} of 446 sec.

A new cryogenic OTV can be based on a growth Shuttle with 75,000-100,000 lb of cargo carrying ability. As an uprated version of the vehicle using dual OTV engines (see F-6) it would be able to make round trips to GEO, either manned or unmanned, with 12,000 lb of return weight. It would employ such new technology as a toroidal O_2 tank, an advanced expander-cycle rocket engine, and possibly aerobraking, along the lines depicted in F-7, which shows an inflatable "ballute" and variable low retrothrust for return to LEO to rendezvous with the Shuttle or a space station. Development of an engine for this approach will be particularly challenging because of the wide range of throttling required: from full thrust down to 5%.

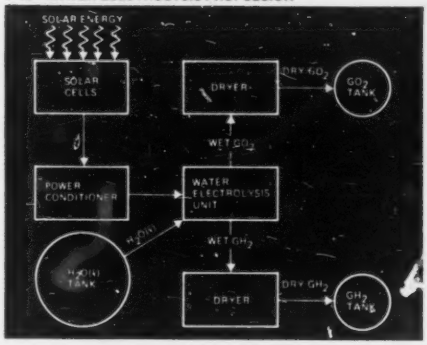
F-8 outlines several other cryogenic OTV concepts being considered by both NASA and the USAF for low-thrust vehicles to transfer very large space systems from the Shuttle to higher orbits. Spacecraft

T-2 LOX/ETHANOL VS. NTO/MMH FOR ORBITER AUXILIARY PROPULSION

System	LOX/ethanol system	NTO/MMH system[a]
OMS RV, fps	600	500
OMS and Aft RCS		
Wet weight,[b] lbm	15,900	17,200
Dry	1,880	2,100

[a] Existing Orbiter OMS and aft-RCS baseline.
[b] OMS RV = 500 ft/sec.

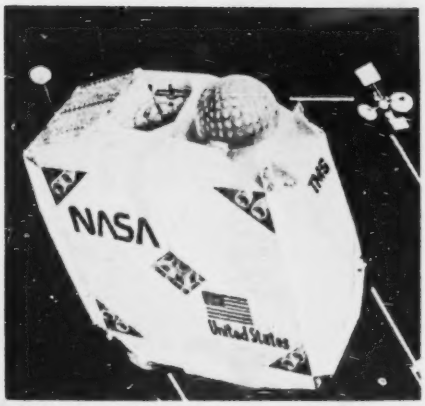
F-10 WATER-ELECTROLYSIS PROPULSION



would be transferred very gently, at low acceleration, allowing transport of very-low-mass structures by employing low thrust (about 500 lbf). They would use cryogenic propellants to maximize payload. A toroidal O_2 tank would reduce OTV length, leaving more space for stowing the spacecraft payload. An optimized low-thrust OTV has many desirable features, but lack of funding may dictate a high-thrust vehicle and significant weight penalties.

Future requirements for increased performance, return trips, and manned sorties will require continued improvements in cryogenic-propellant storability, management, and transfer; use of capillary devices to deliver propellant for restarts; and large and low-mass reusable cryogenic-propellant tanks and toroidal O_2 tanks (see T-1).

Auxiliary Propulsion: Auxiliary propulsion has been a backwater of technical development. Systems used today on various spacecraft, including the Shuttle Orbiter, evolved over the last twenty years and in the main use only two types of propellant—the Earth-storable bipropellant NTO/MMH and monopropellant hydrazine. In both cases, the systems are pressure-fed, with operating chamber pressures in the range of 200 psia or below. These systems have satisfied requirements to date and provide a wide base of flight-qualified hardware; but future missions will demand new operating regimes, higher I_{sp}, much greater total impulse, and longer



F-9 **Teleoperator Maneuvering System,** designed for compact Shuttle carriage, introduces a new level of variable-throttling performance objectives.

life; and they will place a greater emphasis on design safety, toxicity and corrosiveness of propellants, contamination control, refurbishment, accessibility for replacement, and operating costs.

For many satellite applications, hydrazine monopropellant systems will continue to be used because of their inherent simplicity, high reliability, and relatively low hardware cost. Their primary disadvantage—low I_{sp} (in the range of 230 sec)—can be partly overcome by electrically heating the hydrazine decomposition exhaust products to boost I_{sp} into the 300-sec range. (The Intelsat V communications satellite already applies this tactic.) Also, a catalytic reactor can precede the augmentation heat exchanger. This year, Satcom, G-STAR, and Spacenet communication satellites will introduce such augmented systems.

Qualified engines for Earth-storable bipropellant reaction control system (RCS) applications are currently available at the 870- and 25-lb-thrust levels from the Space Shuttle program and at the 100- and 5-lb-thrust levels from the INSAT and Systems Applications Laboratory (SAL) programs. Future applications, such as new geostationary satellites and space platforms, show a requirement for even lower levels. To meet this need, several companies are engaged in bipropellant thruster development in the 0.5-1.0-lbf range. Such low-thrust attitude-control thrusters can be integrated with the larger thrusters used for orbit maneuvering or transfer to achieve greater packaging efficiency and lower cost. Substitution of hydrazine for MMH in existing bipropellant hardware systems has been under evaluation. This would permit using the hydrazine as a

monopropellant from the fuel side of the bipropellant system for reaction control (RCS). The velocity-increment thrusting would be bipropellant (i.e. N_2O_4/N_2H_4). Spacecraft needing extremely low thrust (below 0.5 lbf) from the RCS would especially benefit from this scheme.

Improved Shuttle Orbiter auxiliary propulsion would reduce STS operating costs. One study explored alternative propellants such as LOX/hydrocarbon or LOX/hydrogen in both the orbital maneuvering subsystem (OMS) and RCS. It concluded that better performance could be obtained with a somewhat more complicated auxiliary propulsion system using LOX/ethanol. T-2 compares performance of the current NTO/MMH and the envisioned LOX/ethanol.

The LOX/ethanol system would feature a single turbine to drive both the OMS fuel and oxidizer pumps; separate electric pumps to resupply the propellant accumulators used to feed the RCS primary and vernier thrusters. Liquid propellants would be used for the OMS engine and gaseous oxygen and liquid ethanol for the RCS engines. Heat capacity of the liquid ethanol gasifies the oxygen for the RCS engines. Although the pumps and thermal conditioning increase system complexity, the LOX/ethanol propellants are low in cost, nontoxic, noncorrosive, and will substantially lower operatinal costs. To gain these benefits we must develop the required pump and engine technology.

Wide-range throttling systems are expected to be in greater demand for a variety of space maneuvering involving manned and unmanned movements between the Shuttle, a space station or space platforms, and other spacecraft. Military interceptors will need both pulse-modulated and wide-range, variable-thrust auxiliary propulsion capable of attaining very high response and producing large variations in acceleration.

The NASA Teleoperator Maneuvering System (TMS, F-9) has been optimized for minimum length in the Shuttle cargo bay. It uses eight throttling hydrazine engines. In the planning are growth versions for Earth-storable bipropellant engines capable of thrust variations from 113 to 35 lb.

Future satellites in general, and communication satellites in particular, will require auxiliary propulsion with longer life (over 15 years) and lower cost. Thus the effects of long-term compatibility as well as very high number of operational cycles (mechanical, thermal and pressure) must be better understood. Technology programs are needed to gain more data in the following areas:

- Fracture mechanics of propellant-feed-system materials after long propellant exposure and of thrust-chamber materials after many thermal/pressure cycles.
- Propellant characterization to determine the relation of contamination and degradation to storage specifications, including cleanliness and effects of minor constituents.
- Thermal, pressure, and cycle fatigue in terms of cracking or loss of thrust-chamber materials and coatings.
- Plume contamination for various propellant combinations and physical arrangements.
- Monitoring equipment for leakage and wear-out detection, and propellant depletion to support autonomous operations.

Higher-energy propellants can improve performance. High-density, fluorinated oxidizers with amine fuels (I_{sp}, 460 sec) particularly interest designers for OTVs, space-station elements, and laser weapon systems. While much engine experience has been gained with fluorinated oxidizers, additional development is needed to meet operational flight needs when they are defined for future missions.

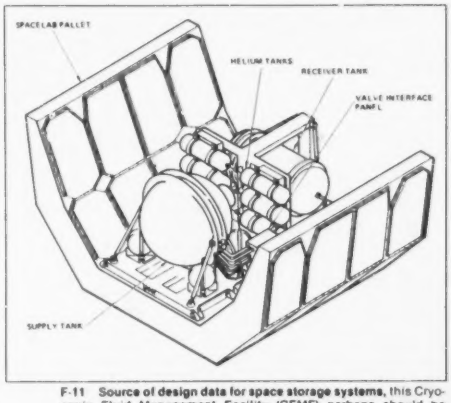
Oxygen and hydrogen will see increasingly greater application for auxiliary propulsion. Pulse-modulated auxiliary propulsion systems will most likely employ gaseous O_2 and H_2 to gain important weight and volume advantages. NASA space-station studies indicate advantages for engines that operate in either gaseous- or liquid-propellant modes. Thus, a 30-lbf gaseous-propellant engine could also be used as a 200-lbf liquid-propellant engine. Using the higher thrust for OTV functions or more rapid maneuvering, and the lower thrust for attitude control and positioning, offers possibilities. But these flight-type O_2H_2 engines using either all gas or gaseous/liquid propellants for auxiliary propulsion must yet be developed.

Thruster technology for very small gaseous O_2/H_2 engines has reached an advanced state and offers extremely small impulse bits (0.001 lb-sec), but much effort will be needed to develop flight-qualified engines. For long-life space systems with large power-generation ability, use of H_2 and O_2 derived from water by electrolysis appears to offer advantages. The water-electrolysis propulsion system (F-10) has already undergone extensive development. Gaseous propellants can also be liquefied at a space station for use in propulsion, emergency power, and life-support subsystems.

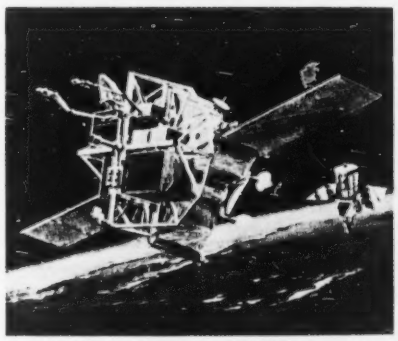
Planetary-Spacecraft Propulsion: Planetary spacecraft have increased in size and thus performance requirements to meet ambitious mission concepts. The Galileo orbiter embodies a propulsion velocity increment (ΔV) of 1700 m/sec —an order of magnitude greater than the early

Mariners. Spacecraft flight times have increased from a fraction of a year to over five years (the Voyager mission). Work in this field has long been devoted to obtaining the necessary performance, and now needs to concentrate on cost optimization. In view of the limited funding available for the immediate future, the major emphasis of the planetary programs will be on low-cost missions.

The current Mariner Mark II (MM II) study seeks cost reductions through multimission spacecraft design. Missions under consideration for MM II spacecraft include Mars and Saturn orbiters, a Titan flyby, comet and asteroid rendezvous, and a comet-sample return. These missions require Galileo-class NTO/MMH propulsion systems, but need supporting technology programs to reduce cost and contamination and to increase reliability. Contamination of spacecraft optics, low-temperature sensors, and heat-rejection systems by the propulsion system is not adequately understood, requiring study of the backflow region, plume and spacecraft structure interactions, and deposition of exhaust products on spacecraft surfaces.



F-11 **Source of design data for space storage systems,** this Cryogenic Fluid Management Facility (CFMF) perhaps should be pushed for earlier launch than the scheduled 1989 date.



F-12 **Teleoperator Maneuvering System (TMS) with remote operations service system gains in cost-effectiveness** by on-orbit propellant resupply, an objective of technology developments.

Manufacturing propellants in space (e.g., oxygen from Martian carbon dioxide) can increase the performance of sample-return and planetary cruiser missions. Long-life, low-mass active-thermal-control systems for liquid-hydrogen storage will also raise mission performance. Such a cryogenic pump-fed system would deliver twice the payload to Neptune as a comparable pressure-fed Earth-storable propulsion system.

In summary, much of the necessary technology is common to the space station, OTVs, and space-based weapons. Coordination of programs will aid efficient technology development.

Space-Based Fluid-Management Systems: Space-based propulsion and reactant storage will require new techniques for storage, resupply, and maintenance to achieve cost-effectiveness in the anticipated long-duration operations. Integrating propulsion and reactant storage brings packaging and weight advantages. The longest subcritical (liquid) cryogen storage in space has been 8 hr and 22 min (Titan/Centaur TC-5 Extended Mission). Mission models covering the next twenty years include on-orbit stay times of five years and longer.

Effective thermal control, integrated with effective low-*g* fluid management will be the key to longer storage. Systems have been developed for storable propellants, but need verification and possible further development for cryogens. Either boil-off in a thermodynamic vent system or active refrigeration of the storage tank and its surroundings can serve thermal-control needs; but the reliability of low-mass refrigeration systems now limits missions.

Other technology needs include long-life insulation with minimized contamination and degradation, tank supports and penetrations to minimize heat leaks, low-*g* gauging systems, low-volume (flow-rate) cryogenic pumps, long cycle life for valves, and reliability of electronics. System issues include development of a protective enclosure for the cryogenic storage system to prevent damage from space debris and to allow fully automated on-board inspection, checkout, and servicing.

The Cryogenic Fluid Management Facility (CFMF, F-11) being pursued by NASA—a reusable

Shuttle test-bed—will use liquid hydrogen as the test fluid to conduct experiments on thermal protection, liquid position control (fluid acquisition), tank-pressure control, fluid transfer and resupply, and gauging of fluids in low-*g* flight. CFMF is not scheduled to be flown until 1989. The growing interest in on-orbit storage and need for design data suggest the need for an earlier flight.

Resupply lowers life-cycle costs and minimizes the use of expendable systems. Cost studies since 1970 clearly show the economic benefits of on-orbit servicing compared to ground refurbishment or expandable systems. Refueling of a space-based OTV has been proposed as one important space-station function. Resupply might make use of an aft-cargo carrier (ACC) on the Shuttle's External Tank (ET). This ACC would have catch tanks for scavenging residual ET liquid hydrogen and LOX. Depending on the Shuttle payload weight, the catch tanks could be partially full during launch for in-orbit transfer and later scavenging, or they could be empty for scavenging from the ET only. At a space station the propellants would be transferred to long-duration storage containers. Alternately, the catch tanks could be designed for long-term storage and merely cascaded together at the space station for OTV servicing.

Fluid-resupply approaches that have been proposed for both Earth-storage and cryogenic propellants include gravity transfer (tanks rotated, with supply and receiver tanks on opposite sides of the center of rotation), positive expulsion (primarily usable with storable propellants and small tank sizes with limited reuse), nonvented fill (to resupply a blowdown system or a pressurized system vented to a lower pressure with no condensable gas), and capillary fluid management (using surface-tension properties to position the liquid, permitting vapor venting with a gravity field). Fluid-resupply technology needs include remotely operated nonleak transfer-line disconnects, mass gauging for continuous system monitoring during the fill process, standard carrier-plate interfaces, connectors to mate with Shuttle-contained resupply servicing systems, and long-cycle-life leaktight valves to prevent propellant migration (e.g., to pressurant tanks).

Repair or replacement of components and subsystems helps meet life requirements and lessens the need for redundancy. Filled propellant tanks as modular replacements fall in this category for the smaller propulsion systems. A key issue is autonomy vs. man-in-the-loop operations. The Solar Maximum Mission spacecraft will be repaired by an astronaut using the manned maneuvering unit. A teleoperator maneuvering system (TMS), on the other hand, will retrieve satellites and return them to the Orbiter for servicing or Earth return. When mated with service modules, such as the Remote Operations Servicing System, TMS will provide routine or contingency on-orbit servicing, maintenance, and reconfiguration operations while remotely controlled from a ground station. Resupply of the TMS propellants increases its cost-effectiveness. In all this work, technological advancements in on-orbit storage and resupply—a key to cost-effective space operations—need to be pressed for timely incorporation into flight systems.

Concluding Remarks: Since the advent of Sputnik in 1957, the United States has repeatedly emphasized its policy to maintain world leadership in space technology. Our nation continues to lead the world in rocket propulsion, but the systems now in use are products of R&D programs begun over a decade ago. We have no major technology programs in active support of advanced propulsion concepts. The AIAA Liquid Propulsion Technical Committee (TC)—through its own studies, its assessment of planning activities within NASA, DOD, industry, and participation in reviews of USAF space-technology (MSSTM) requirements—concludes that *future programs have a common need for advanced-propulsion-system development to realize their objectives in a cost-effective manner.* This requires an adequate federally sponsored R&D program committed to optimal liquid-rocket systems insuring minimal risk technology readiness.

Five basic categories of liquid-propulsion systems require technology advancement:

- Launchers and boosters.
- High-performance orbit-transfer and planetary-injection systems.
- High-performance space-storable maneuvering systems.
- High-performance auxiliary systems.
- Long-term space fluid storage, resupply, and maintenance.

Without a renewal of liquid-propulsion technology, the nation will not achieve it needed goals of performance and cost-effectiveness in coming space systems. It is in the nation's interest to maintain and expand the existing technology base. Further, because advanced liquid-rocket systems require lengthy development, the Committee finds an *immediate* need for technology programs that will raise mission performance and simultaneously cut launch costs. A small continuing investment throughout the 1980s will greatly reduce the development costs of future space systems. The federal government, as the principal user of space systems, should begin the investment now.

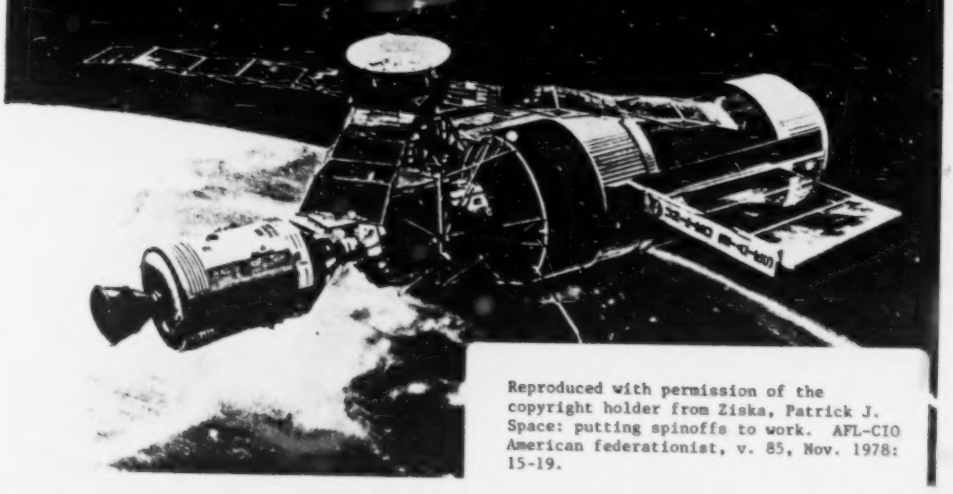
Space: Putting Spinoffs to Work

by Patrick J. Ziska



Reproduced with permission of the copyright holder from Ziska, Patrick J. Space: putting spinoffs to work. AFL-CIO American federationist, v. 85, Nov. 1978: 15-19.

On July 20, 1969, humankind broke through the cocoon that had confined it to one planet for 4.5 million years. On that day we humans stopped being an earthbound colony and started becoming space-destined butterflies. On that day two Americans walked on the surface of the moon, while millions of other Americans watched with awe in their homes. And on that day the once wild fantasies of science fiction began being translated into the realities of practical science applied.

For many thousands of American workers, the moon walk was of special interest and unique pride. They and their skills had helped make the moment possible. Their contributions had demonstrated to even the skeptical that as the future becomes the present, science and craftsmanship have found a way to catch up with what had been space fiction.

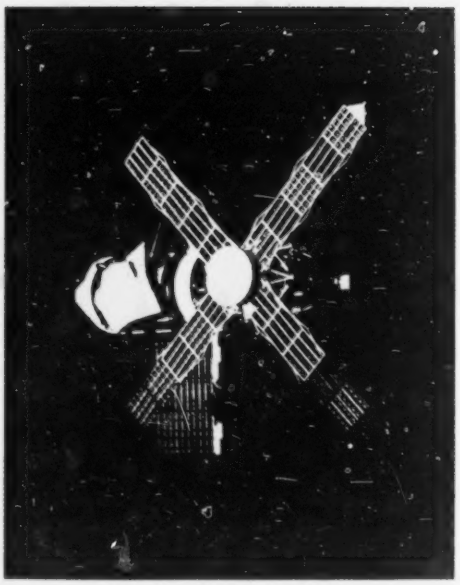
In the years since that historic moon mission, America's fascination with the final frontier propelled space adventure into almost a second national pastime. For instance, interest in space fiction, which somehow seems to cease being fiction and start being fact with the passage of time, has made the movie Star Wars into the biggest box office attraction ever, grossing $220 million in its first year of release. The sale of Star Wars memorabilia such as T-shirts and bubble gum has grossed another $200 million. And when space fans are not watching such adventures, they are reading about them. This year Americans spent $45 million on space books, fact and fiction, compared with only $1.5 million in 1968.

While Americans have made space adventure a hobby, more than 100,000 workers have quietly nudged space technology from adventure to practical application. These workers, members of nearly every U.S. union, are part of the team that has brought us from Explorer I to the moon. Now these skilled workers are moving the nation closer to the final frontier with their work on space labs, space freighters and—sooner than many now believe—to space colonies.

In the first two decades of space technology since America's first satellite, Explorer I, went hurtling into space, this team has contributed both to the nation's economy and its technology.

Dr. Robert A. Frosch, administrator of the National Aeronautics and Space Administration (NASA), de-

PATRICK J. ZISKA is an associate editor of The Machinist.



scribed some of the contributions of organized workers this way: "This is the team which took us from Sputnik to the moon in an incredible dozen years; which so precisely soft-landed the Viking spacecraft on Mars; which has dispatched the Pioneer and Voyager probes on their long planetary explorations; which created the High Energy Astronomy Satellites whose sensors are investigating the far universe; and which is developing the Space Transportation System, throwing the door to space wide open for the decade of the 1980s and beyond."

Frosch notes that NASA spends more than 80 percent of its budget on labor intensive contracts and current programs employ more than 100,000 workers.

But the jobs impact is only one factor in the nation's ongoing space program. Equally important is the maintenance of U.S. technological leadership in the world community. Space research also has helped improve the current generation of commercial aircraft for the nation's travellers and is laying the foundation for the more advanced planes now on the drawing board to replace a generation of aircraft growing old. This technology will enable aerospace companies to advance their technology to meet the needs of the nation's airlines for an estimated $75 billion in new planes in the next decade.

Besides these obvious benefits, thousands of indirect benefits from secondary applications of space technology occur.

These benefits, or spinoffs as they are called by NASA, range from simple conveniences to major systems that help solve critical problems. They can save the seriously ill from death. They include satellites which beam sports and cultural events from Europe to our homes. They include life-saving, two-way communications transmitting a heart attack victim's cardiogram from an ambulance to a hospital. NASA calls these spinoffs a "tale of technology twice told."

Space technology has been transferred to medicine, transportation, public safety, energy and pollution solutions, construction, communications, industrial and agricultural processes, sports and recreation and to nearly every avenue of everyday life.

And within these broad categories, there have been thousands of individual spinoffs.

Critics of the space program point out some of the more frivolous applications such as the crystal candy which when dissolved in water forms a gravity free beverage.

But they either ignore or are unaware of the many more serious spinoffs. In the field of medicine, space technology has provided life saving equipment aiding humanity from birth to brushes with death.

The technology developed primarily to heat faceplates for pressure units in space are now adapted and used in post-delivery care of infants born prematurely or with respiratory problems. Automated blood pressure measurement, another spinoff, enables untrained personnel to monitor ill relatives and friends. Space communications systems aid patients enroute to hospitals after heart attacks and other medical emergencies, saving vital time particularly when the scene of the emergency is remote from the hospital. Similar systems enable nurses to monitor large numbers of patients in intensive care units.

Heated transparency technology, originally developed for use on space vehicle faceplates and cockpit canopies, is now working to save burn patients discomfort and more serious complications. An important factor in burn treatment is keeping the patient warm to counter hypothermia, a state of low body temperature characteristic of burn patients. Sheets and blankets cannot be used and until the development of the special canopy, it was necessary to suspend coverings over hoops encircling the patient's bed. Even so, burn victims complained of cold. The problem involved more than discomfort. Shivering uses up large amounts of energy needed to fight infection and renew damaged cells. The Apollo Radiant Warmer, an over-the-bed canopy, provides the warmth without the discomfort or danger of infection or unwanted weight loss caused by excessive shivering. The heat is provided by emitting uniform, controlled radiant heat to the patient.

Space technology applied to medicine is used in

scores of other ways, to analyze X-ray films, in hearing aids and testers and in other areas of preventive, diagnostic and curative medicine.

Workers exposed to microwaves have a new tool to detect microwave radiation hazards. NASA technology has now made commercially available a new, inexpensive device to measure the radio emissions of extremely high frequency. Thus workers can determine if they are being exposed to more than the allowable threshold set by the Occupational Safety and Health Administration (OSHA).

Secondary applications of safety devices first used in space cover everything from fire detection equipment to heat resistant paint to life rafts which cannot be overturned. Because of safety features on manned spacecraft, homeowners, miners and other workers are enjoying sophisticated early-warning fire detection sensors. Space technology also provides other danger detectors including one to "read" carbon monoxide levels. It has also developed an instrument which protects against electrical shock in home and workplace.

Home protection is improved by yet another detector, this one to pinpoint an intruder. Still another space development with life-saving potential is the satellite search and rescue system, a method of monitoring and locating distress signals from downed aircraft or troubled ships. This package picks up beacon signals, measures their direction of source and relays it to a rescue coordination center.

Space scientists were not surprised by last year's water shortage on the West Coast. Landsat photos had shown the watershed inventory was dwindling well before it happened. Landsat is an earth survey satellite whose sensors detect light waves reflected from the earth. These waves are then translated into images that allow analysts to view the surface of the globe in new perspective. Large portions of the earth may be studied at one time and terrestrial features that cannot be seen by the human eye are studied for changes of earth conditions. Thus they can take watershed inventories, study changing ocean conditions and forecast conditions for shipping, fishing and oil industries. Such satellites can also foresee other changing earth conditions such as imminent earthquakes and warn of impending hurricanes and tornadoes. The list of applications in this area is lengthy and growing. It includes pollution detection, plotting changes in ecology after disasters such as forest fires and improving the accuracy of maps.

Space technology has also provided for a better leisure life. Fans of the Detroit Lions, for instance, do not worry about game day weather. Their Pontiac Stadium has a domed, air supported, fabric roof that admits light but protects the playing field and patrons from the elements. The 80,000-seat stadium is the world's largest fabric-covered structure, and aerospace technology played an important role in its construction. The Detroit "cover" cost $10 million and enabled the city to build its stadium for under $56 million compared with a cost of $168 million for the Superdome in New Orleans. The flame resistant, all-weather material used in Pontiac was a fabric adapted from Appollo astronauts' space suits.

Perhaps the most vital potential benefit from space technology is providing an energy deficient earth with electricity from the sun.

The key to making this proposal reality is the solar power satellite. While other sources of energy—nuclear, coal and other fossil fuels—are being mined, the nation is looking toward the sun as a potential energy donor.

By harnessing its rays in space, and transforming this power into electricity useable on earth, the nation could tap a power as durable as humankind. The potential for accomplishing this feat is the solar satellite, a spacecraft the size of a small city. The satellite would be able to produce twice as much useable power as that generated by the nation's largest hydroelectric dam at Grand Coulee on the Columbia River in Washington state. Forty-five such satellites could match the present total electrical generating power of the nation. If they were in operation, oil, coal and their derivatives would be freed for other uses. As envisioned by space planners, the satellites would be deployed 22,000 miles above the earth's equator. They would work by transforming the sun's rays into electricity and convert this to microwaves which would be beamed to large antennas on earth. These antennas would reconvert this power, providing electricity for the nation's power grid.

Experts calculate that the initial cost of such a space powerhouse would be about $7.6 billion in 1974 dollars. Each subsequent satellite would cost less. The total investment could be repaid with about 60 satellites.

Before these satellites can be built and used, questions about ecology and practicality must be answered. Although many aerospace companies have studied the feasibility of solar satellites and offered plans on how to construct them, much research is still needed. That is why some AFL-CIO unions pushed for legislation in the 95th Congress to appropriate and authorize $25 million for research and development of a satellite system. Among the questions such research would have answered was whether the microwave transmission of energy could be accomplished safely. The bill passed the House, but died before the Senate could act on it. The same bill will be introduced in the 96th Congress.

Obviously, if research shows that satellites are economically and environmentally feasible, the next question would be where to build them. Such spacecraft, measured in miles rather than feet, cannot be launched like an Apollo mooncraft. The solar satellites would have to be constructed either in low earth orbit for later shipment to the higher orbit, or would be constructed directly at the higher orbit site.

Whichever way were chosen, a space freighter

would have to convey the personnel and material. That's where the space shuttle would come in.

The development of the shuttle marks what many observers consider the second space era, less glamorous than the walk on the moon, but much more practical. The second space era has been likened to the discovery of the wheel. The era will highlight space transportation, leading to energy pumping satellites and space colonies.

The past two decades brought the feat of a man stepping on the moon as 500 million viewed it on television or listened on the radio. In the dawning second space era, man will transport laboratories, satellites and colonies (and their colonists) and many more millions will benefit.

In this way, the space industrial society will begin, marking what may be the most significant wonder in human history. The bridge that will carry us to this era is the space shuttle. Its first manned orbital flight is now less than a year away. The shuttle will carry a cargo or payload of 65,000 pounds. Its mission will be to deliver this payload into high earth orbit or into lunar or planetary trajectories.

This cargo will be carried in the shuttle's orbiter. The orbiter spacecraft is about the size of a DC 9 commercial jetliner. It weighs about 75 tons and measures 122 feet in length. The orbiter can carry, along with the cargo, a crew of seven, including scientific and technical personnel.

Because the orbiter will provide for a standard sea level atmosphere inside, any reasonably healthy space worker or other person can be a comfortable passenger. On the first missions, the orbiter will be able to remain in orbit for up to seven days. Then it will return to earth, be refurbished and be ready for another launch within 24 hours. Other shuttle components besides the orbiter are an external tank and two solid rocket boosters. The external tank contains the ascent propellant. Both the orbiter and the boosters are reuseable, the orbiter is good for at least 100 missions. The boosters, which burn in parallel with the orbiter's main propulsion system, are separated from the orbiter when the vehicle is about 24 miles high. Then the boosters are dropped by parachute into the ocean about 150 miles from the launch site at Kennedy Space Center. When the orbiter's mission of delivery to space satellites or maintenance of such satellites is finished, re-entry is made into earth's atmosphere. The orbiter is then landed with a horizontal approach and touchdown similar to that made by conventional aircraft. Workers are now swarming over the huge launch complex at Kennedy preparing for the next exciting chapter of space history. That launch is now scheduled for mid-September 1979.

The shuttle then will be more than just a space freighter. It will be used to retrieve payloads from orbit, to service and maintain satellites and to operate space laboratories. NASA officials also look toward the day when the shuttle will be carrying workers to space colonies.

As envisioned by Dr. Gerard K. O'Neill, professor of physics at Princeton, this could happen as early as the 1990s.

Several designs for permanent space stations already have been developed. One design calls for a station comprised of cylinder type modules. Eight of these modules joined together could accommodate a workforce of 50. One such module could easily fit into the cargo bay of the shuttle now being prepared for launch.

Our ability to put people into space and to maintain them there in good health began with the Apollo moon landing project. The Skylab project of the early 1970s extended the time limit for astronauts in space to three months.

According to O'Neill, the maintenance of life for "a time of as many months as would be necessary for a voyage to the asteroids, presents no problems which are new in principle."

The asteroids, thousands of small planets most lying between Mars and Jupiter, are rich in ores. If these asteroids could be mined, as futurists now propose, the earth could benefit with a 200-year supply of nickel and enough steel for many years.

Using the shuttle as the primary means of transspatial travel, much as the wagon trains were the first mode of trans-continental transport, O'Neill sees the possibility of traveling through space in "a tugboat and a string of barges. In space there is no drag," he says, "the tugboat would be needed only at the start and end of each trip, and during the long months of the orbit . . . could travel unmanned."

O'Neill also writes a scenario about a husband and wife living near the close of the 20th Century on a space colony. There they work and live, coming back to earth for periodic vacations.

In a "letter" back to friends on earth, O'Neill's space couple writes: "It's a comfortable life here. Fresh vegetables and fruit are in season all the time, because there are agricultural cylinders for each month of the year, each with its own day-length. We grow avocadoes and payas in our own garden, and never need to use insecticide sprays. Of course we like being able to get a suntan without ever being bitten by a mosquito. To be free of those pests, it's worth it to go through the inspections before getting aboard the shuttle from earth."

The fictional writer of the "letter" is a construction worker and his letter indicates that space colonies will have the same problems as earth communities. The need for space trade unions is apparent.

If, as O'Neill and many other space experts predict, workers will be living on space colonies by the year 2000, there may well be delegates from such exotic places as Space Colony Alpha at the 21st Century's first AFL-CIO Convention.

If that sounds farfetched in 1978, so did the concept of men walking on the moon when it was proposed 22 years ago.

LETTER OF TRANSMITTAL

U.S. SENATE,
COMMITTEE ON COMMERCE, SCIENCE, AND TRANSPORTATION,
Washington, D.C., September 23, 1983.

DEAR COLLEAGUE:

The Committee on Commerce, Science, and Transportation and the Subcommittee on Science, Technology, and Space are pleased to submit this report on the policy and legal issues associated with the commercialization of space. Information in this report was originally requested of the Congressional Research Service by Senator Hollings.

This report is particularly timely given the decision by the President in March 1983, to pursue the transfer of the weather and land remote sensing satellites to the private sector and his May, 1983, announcement that the Government will facilitate commercial operation of Expendable Launch Vehicles.

The Committee and the Congress have approved legislation which would require Congressional participation in the implementation of any plan to commercialize these national assets. It is not the purpose of the legislation or the intent of the Committee to foreclose the options for commercialization; rather, there is a legitimate Congressional interest in the proposals such as to require timely and open participation in the decision process.

The commercial promise of space is being realized. Our first revolution is in communications; the next could be in materials processing or terrestrial observations, as examples. Government has led and continues to lead the research and development, but commercialization is primarily a private sector responsibility. We have not yet determined when, how or what governmental responsibility should be relinquished so that the public benefit will be optimized.

The report which we are releasing sheds additional light on the problems and issues of commercializing space activities. The effective resolution of these issues will be of major importance to our national security and economic well-being.

Cordially,

BOB PACKWOOD,
Chairman, Committee on Commerce, Science, and Transportation.

SLADE GORTON,
Chairman, Subcommittee on Science, Technology, and Space.

LETTER OF SUBMITTAL

U.S. SENATE,
COMMITTEE ON COMMERCE, SCIENCE, AND TRANSPORTATION,
Washington, D.C., July 20, 1983.

Hon. BOB PACKWOOD,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: I am pleased to transmit a report by the Congressional Research Service, prepared at my request, evaluating the legal and policy issues involved in space commercialization.

One of the significant areas of continued U.S. international leadership is space. With the successful operation of the Space Shuttle, we now have a capability to utilize space on a routine basis. This will help lead the way to enormous economic and commercial benefits. As a Nation we must be prepared to pursue the opportunities in such areas as launch services, communications, remote sensing and materials processing.

In entering this new commercial era of space, we are likely to encounter various policy and legal questions. This CRS report should help the Congress and others indentify those questions and various options to deal with them. I hope this report will be made available widely.

With kindest regards, I am

Sincerely,

ERNEST F. HOLLINGS, *Ranking Democrat.*

Enclosure.

CONGRESSIONAL RESEARCH SERVICE,
THE LIBRARY OF CONGRESS,
Washington, D.C., May 12, 1983.

Hon. ERNEST F. HOLLINGS,
U.S. Senate,
Washington, D.C.

DEAR SENATOR HOLLINGS: Pursuant to your letter of January 17, 1983, we are herewith providing a study entitled "Policy and Legal Issues Involved in the Commercialization of Space." The report was prepared by Marcia S. Smith, Specialist in Aerospace and Telecommunications Systems of the Science Policy Research Division, and Daniel Hill Zafren, Specialist in American Public Law of the American Law Division.

We hope that this study will be useful to you in assessing the implications of space commercialization activities in your role as ranking minority member of the Committee on Commerce, Science, and Transportation.

If we can be of further assistance, please let us know. With best regards,

Sincerely,

GILBERT GUDE, *Director.*

SUMMARY

In 1982, President Reagan announced that it is U.S. policy to "expand U.S. private-sector investment and involvement in civil space and space related activities." To accomplish this goal, the administration must be prepared to consider alternatives such as providing Government subsidies to encourage commercialization and giving the National Aeronautics and Space Administration (NASA) additional funding and direction to organize itself for assisting in the commercialization process. The latter is particularly important in the areas of educating and communicating to industry what opportunities already exist, and performing research and development necessary for creating a basis on which companies can decide to enter the space business.

The legal and policy issues involved in this developing area are many, and while some have been discussed in the past, the recent surge in proposals from private companies has spurred a new urgency for their consideration and expeditious resolution. Among the issues discussed in this report are:

— The need for NASA to better organize itself for its role in commercial space endeavors in terms of centralizing responsibility, clarifying the types of agreements that are needed/desired with the private sector, and communicating with the private sector;

— The dilemma NASA faces in trying to encourage private sector interest in space endeavors, such as the commercialization of expendable launch vehicles, while protecting its own interests;

— The possible interpretation of the National Aeronautics and Space Act that all private sector space activities must be carried out under NASA's aegis;

— The need for coordination among the various Federal agencies with responsibilities in commercial space ventures, with the potential of designating a lead agency, and between the Federal Government and State and local governments.

— The choices which must be made by the Government between the desire to commercialize space and the potential cost of subsidizing such ventures, and maintaining competitiveness with other countries at the same time;

— The proper role of the Government vis-a-vis the private sector in performing advanced research and development on "commercial" systems;

— The need to regulate private sector space activities, both for safety and for conformance with international treaty obligations;

— The impact of national security requirements on commercialization proposals;

— The need to clarify responsibilities, obligations, funding, contributions, and claims procedures for liability associated with space ventures; and

— The need to reassess patent law to encourage commercialization.

The President's policy is to expand private sector involvement in space, but such activity is not without financial risks to the Government, not only if subsidies are required, but if a commercial venture fails and the Government must buy back into the system. Thus the first important step is to decide if commercialization is worth that risk. If the answer is yes, then the resolution of the other issues can follow.

PART I: POLICY ISSUES INVOLVED IN THE COMMERCIALIZATION OF SPACE

Prepared by Marcia S. Smith, Specialist in Aerospace and Telecommunications Systems, Science Policy Research Division, Congressional Research Service.

INTRODUCTION

Once solely the province of Government-funded research and development, space technology has become an area of increasing involvement by the private sector, not only in terms of R&D, but also in commercial applications.

For many years, NASA has fostered the transfer of space technology to the private sector through technology transfer and utilization programs such as COSMIC (a computerized program for making available to anyone research accomplished at NASA), yielding "spinoff" benefits such as rechargeable pacemakers for the heart. These secondary applications of NASA technology have been extensively detailed in many publications (such as NASA's annual spinoff books).

Recently, however, the private sector has begun showing interest not just in these applications of space-derived technology, but in becoming part of the space business itself. Several companies are actively pursuing the possibility of marketing expendable launch vehicles once NASA phases out their use in favor of the Space Shuttle, while others are involved in cooperative endeavors with NASA to develop processes and hardware for manufacturing materials in space. Companies have also come forward with plans to build space facilities such as a space station in cooperation with NASA. Other private sector activities would involve the takeover of operations of systems which have successfully completed the R&D stage. As with communications satellites, there is now a possibility of the private sector operating land remote sensing and weather satellites, as well as the Space Shuttle once it is fully operational. A summary of space commercialization proposals appears in the appendix.

As this "commercialization" of space takes root, a number of policy issues will have to be addressed. These include: The proper role of the Federal Government versus the private sector in research and development programs, and how to determine when the R&D is completed and a system is operational (and therefore ready for the private sector); how much (if any) of a subsidy should be provided by the Government to assist in commercial opportunities; methods for the Government to encourage space commercialization without creating harmful competition to itself (in providing launch services, for example); how to keep the United States competitive with foreign space ventures; what regulations (if any) are required for commercial activities in space and what agency should be in charge of these regulations; and what the national security implications of commercial activities may be.

4

NASA is currently developing policy guidelines for the commercialization of space and has contracted for two studies (by the National Academy of Public Administration and the Denver Research Institute) in addition to its in-house studies. Policies are expected to be announced during 1983.

This part of the study identifies policy issues which might be involved in certain areas of space commercialization, including remote sensing, expendable launch vehicles, the Space Shuttle, and materials processing in space. Legal issues are discussed in part II of this report.

Communications Satellites—A Case Example

In looking for precedents of where a space activity has successfully been turned into a commercial enterprise, the only example at this time is communications satellites. Only two other fields of space activity have reached what can be considered an "operational" status—weather satellites, and land remote sensing satellites—and both of these are still operated by the Government, although not by NASA.

Considering that the first U.S. communications satellite, Echo, was launched only in 1960, it is remarkable that the potential of this type of endeavor was recognized so quickly and turned into a commercial endeavor. It took less than 2 years from the October 12, 1960 announcement by NASA that it would launch and evaluate private communications satellites to the enactment of the Communications Satellite Act on August 31, 1962. [1]

The intense interest of the private sector in creating a commercial communication satellite system was evidenced by AT&T's application to the Federal Communications Commission (FCC) for authority to do just that on October 21, 1960, barely 2 weeks after the NASA announcement. On January 19, 1961, FCC granted AT&T the authority to establish an experimental transatlantic satellite link. On February 26, 1961, NASA and FCC released a memorandum of understanding in which FCC was identified as having the policymaking role in this area. [2]

FCC issued a notice of inquiry (NOI) on March 29, 1961 to receive views regarding the administrative and regulatory structure of a commercial communications satellite system. Seven proposals were received in response to the NOI, as well as a filing from the Justice Department outlining several antitrust considerations it wanted taken into account: The need for joint ownership by all carriers, for nondiscriminatory access to the facilities, to permit ownership by any interested equipment suppliers, and to assure competitive procurement of equipment.

Following a May report based on the responses to the NOI in which it essentially proposed that satellites be treated similarly to

[1] Some of the information in this section is condensed from part of a study by the Science Policy Research Division of the Congressional Research Service prepared for the House Committee on Science and Technology entitled "U.S. Civilian Space Programs Volume II—Applications Satellites," which is in press.

[2] Memorandum of Understanding Between FCC and NASA On Respective Civil Communications Activities. Feb. 28, 1961. Published in U.S. Congress. House Committee on Interstate and Foreign Commerce. Communications Satellites. Pt I. 87th Cong. 1st sess. Washington, U.S. Government Printing Office. 1961. pp. 6-7.

undersea cables (as facilities jointly owned by their users), the FCC sponsored an industry conference at which it was agreed to create a committee to formulate the terms, conditions, and operational structure of the system. The committee was composed exclusively of common carriers.

Concerned about the FCC proceedings, President Kennedy wrote to Vice President Johnson on June 15, 1961 and directed him to conduct a study on how, and under what structure, to establish an operational system at "the earliest practical time." [3] Much of the work was performed by the National Aeronautics and Space Council (NASC) in consultation with industry and Government agencies. The NASC report was delivered to the President on July 16, 1961 and recommended private ownership of the U.S. portion of an international communication satellite system, coupled with Government controls to prevent monopolization.

On July 24, 1961, President Kennedy issued a communication satellite policy based on the NASC recommendations, calling for nondiscriminatory access to the system, competitive bidding in the acquisition of equipment, and foreign participation through ownership. [4]

During this time, congressional hearings had begun on the proposal. Held in June, July, and August 1961, they focussed on concerns about potential AT&T monopolization of the system. In October 1961, the FCC-established committee of common carriers issued its report, recommending a nonprofit corporation owned by AT&T and the international record carriers, with the system itself being run by the corporation but each carrier owning its own ground stations.

By the time legislation was introduced in early 1962, arguments over how to approach this issue had coalesced into basically three types of reasoning. One group argued that since the technology had been developed at Government expense, and that one of the goals was to demonstrate U.S. capabilities and good will, then the Government should own and operate the system. Another faction insisted that private companies would be more effective, as evidenced by the fact that, in their view, the United States had the best and cheapest communications system in the world. The third line of reasoning was that although the private sector might be more efficient, there was the danger of monopolization by existing private firms so a new approach was needed—a public corporation.

Three bills were introduced: One at the request of the administration creating a profitmaking, quasi-public corporation with limited ownership interest by the international common carriers, but with real control vested in voting stock controlled by the public; a second by Senator Kerr, chairman of the Aeronautical and Space Sciences Committee, creating a satellite communications corporation owned and operated exclusively by the international carriers; and a third by Senator Kefauver providing for Government ownership of the system.

After extensive congressional hearings (including 9 days by Kefauver's Subcommittee on Antitrust and Monopoly in the Senate

[3] New York Times, June 25, 1961, p. 35.
[4] Department of State Bulletin, Aug. 14, 1961, p. 273.

Judiciary Committee, even though no legislation concerning the issue had been referred there), a filibuster on the Senate floor and an historic cloture motion, the 1962 Communications Satellite Act was passed by the Senate on August 17 and the House on August 27, 1962. The President signed the legislation into law on August 31 (Public Law 87-624).

The 1962 act led to the creation of the Communications Satellite Corporation—Comsat—in 1963. As codified in the act, Comsat would be a private corporation in order to use the profit motive to spur development, would have a broad international charter to enable a global system to evolve, including those services which might not immediately show a profit, and would be organized and operated to preclude domination by a single company through ownership or patent control by having 50 percent of the stock owned by the public, and the other 50 percent by the international carriers.

In essence, Comsat was formed as a publicly owned company with Presidential supervision in the foreign policy area. FCC was directed to ensure effective competition in the purchase of telecommunications goods and services by Comsat, and to regulate the allocation of facilities by Comsat to the satellite system users. In addition, Comsat was required to provide Congress and the President with an annual report of its activities, operations, and accomplishments, and it was to be a "carrier's carrier," meaning that it could not offer services directly to users. The act authorized Comsat to provide goods and services associated with communications services and was initially interpreted as restricting Comsat to that role.

When it passed the International Maritime Satellite Telecommunications Act in 1978, which made Comsat the U.S. signatory to Inmarsat as well as Intelsat, Congress included language directing the FCC to determine whether changes were required in Comsat's structure or operations to ensure that it could fulfill its obligations under the 1962 act. The study, released in 1980, [5] addressed a number of issues, including whether Comsat should remain a carrier's carrier and whether Comsat was prohibited from entering fields other than those related to communications satellites. As noted above, the 1962 act expressly authorizes Comsat to offer communication services, but does not specifically preclude it from entering other areas.

The FCC study concluded that Comsat should be released from its carrier's carrier restriction and that it could provide services directly to end users. Also, the study concluded that Comsat could engage in any activities which are not inconsistent with its statutory mission providing that there is no cross-subsidization between Comsat's regulated services and new competitive services it might begin. An August 1982 FCC memorandum opinion and order issued after comments had been received on the 1980 study reaffirmed this position. [6] This allows Comsat the flexibility to enter other areas, such as the commercialization of remote sensing satellites in which the company has already expressed an interest.

---

[5] Final Report and Order (Comsat Study), FCC 80-218, Apr. 22, 1980.

[6] Changes in the Corporate Structure and Operations of the Communications Satellite Corporation. CC Docket No. 80634; FCC 82-372. Released Aug. 13, 1982. Federal Register, vol. 47, no. 181, Sept. 17, 1982. pp. 41116-41135.

The example of how communications satellites became a commercial success is not necessarily directly relevant to today's efforts at space commercialization in other areas, however. First, there was a clear market for the communications services which Comsat was created to provide, something which is not evident today in enterprises such as materials processing in space or remote sensing. Second, a major motive for enacting the legislation was to create an international system, while today's debate concerns U.S. domestic businesses (which might serve the international market, but are not specifically designed for that purpose).

Provisions of the act which may be relevant to the current debate, however, include language such as section 102 which states that it was Congress' intent that "all authorized users shall have nondiscriminatory access to the system," and that Comsat be "organized and operated as to maintain and strengthen competition in the provision of communications services to the public." These principles might well be incorporated into commercial satellite systems for purposes other than communications.

Selected Areas for Study

For the purposes of this report, four areas have been selected for examination: remote sensing satellites, expendable launch vehicles, materials processing in space, and the Space Shuttle. Each is a current topic of discussion in terms of commercial opportunities in space and each presents unique as well as complementary policy issues.

REMOTE SENSING SATELLITES

NASA has developed three types of satellites for remote sensing of the Earth from space: Landsat and Seasat whose names are self-explanatory, and weather satellites which are designated NOAA for the National Oceanic and Atmospheric Administration which operates them along with Landsat. Only one satellite was launched in the Seasat program, and it failed after 100 days in orbit; Government proposals for launching future satellites have been indefinitely postponed.

The land and weather satellites are at the center of a debate on how best to commercialize satellite systems. Although there continues to be controversy over the precise meaning of NASA's charter, there is general agreement that NASA's prime mission (if not its only mission) is research and development (R&D) rather than operations. Thus, when the weather satellites reached an operational status, they were transferred to the Environmental Satellite Services Agency (ESSA) in the Department of Commerce, which later became part of NOAA. NASA retained responsibility for weather satellite R&D and launched several more experimental satellites after control of the operational segment was transferred to Commerce.

When it was determined that the Landsat program could also be declared operational, President Carter decided to give that system to NOAA as well. [7] His plan envisioned eventual transfer to the

[7] Presidential Directive 54, November 1979.

private sector over the course of a decade. Early in 1981, the Reagan administration indicated that it wanted to speed up that transfer timetable. This was the first step in a growing controversy which was greatly broadened when Comsat suggested that weather satellites be included in any transfer arrangement to the private sector.

In response to the Comsat suggestion, President Reagan directed the Cabinet Council on Commerce and Trade (CCCT) to study the feasibility of transferring Landsat and the weather satellites to the private sector. After an initital decision in April 1982 that the weather satellites should remain in the Government, the CCCT was asked to reassess the matter and subsequently recommended full commercialization of land, weather, and ocean satellites. As part of the CCCT reassessment, the Department of Commerce issued a request for information (RFI) from the private sector on whether and how to commercialize Landsat and/or the weather satellites. Only Comsat recommended full commercialization of both the land and weather satellites, and indicated that it was also interested in any future ocean satellites. Other companies indicated interest in parts of the Landsat and weather satellite ground segments, but not in the satellites themselves, and generally concluded that the full transfer of Landsat should take place over a period of time. One company, American Science and Technology (AS&T), expressed interest in the Landsat command and control segment, but expressed a preference for launching its own, privately developed land remote sensing satellites. AS&T sees a need for specialized remote sensing services (such as for oil companies searching for telltale geological formations which indicate oil deposits) and it plans to launch three small satellites using a privately developed launch vehicle called Conestoga. Space Services, Inc., developer of the Conestoga, is a majority shareholder in AS&T.

The major problem in commercializing Landsat is the lack of an identifiable market for the data products which would assure a company of making a profit. Comsat's solution to this problem was the suggestion of including weather satellites in the deal, since the Government itself would buy 95 percent of the data. The Comsat response to the RFI included possible terms that it would make in an offer for the land and weather satellites: Payment of $250 to $350 million for existing satellites and ground equipment, plus a guaranteed Government purchase of approximately $300 million of data every year for 15 years. The latter condition could be considered a Government subsidy, and it has also been pointed out that Comsat could get a significant tax break by investing in the new system.

The problems involved in the transfer of remote sensing satellites to the private sector have been extensively discussed in many sets of congressional hearings since 1973 (the year after the first Landsat was launched) and reports.[8] They need not be restated here, since the main purpose of including remote sensing in this discussion is to assess the current problem with commercializing

[8] See for example: Landsat—Earth Resources Satellite System, CRS Issue Brief 82066, and Commercialization of Landsat and the Weather Satellites, CRS Issue Brief 83072.

satellites in comparison with the case example of communications satellites discussed previously.

First, one clear difference is that communications satellites had a developed market for their services and Landsat does not. This has led to the question of how much, if any, subsidy should be provided in order to increase the commercial attractiveness of the system. Also, without a clear profitmaking market, there is always the possibility that the private entity would terminate its involvement if the program lost money, raising the question of how much it would cost the Government to buy back into the system.

The issue of commercializing Landsat has been complicated by Comsat's suggestion to include the weather satellites. Although it has its own meteorological satellites, the Department of Defense (DOD) uses the NOAA weather satellites on occasion, thus raising national security issues if the weather satellites are operated by the private sector. A transfer of Landsat to the private sector also presents national security issues, but these might have been dealt with more readily without added concerns about weather satellites.

The concern of the public was raised by the announcement to transfer weather satellites to the private sector, both in terms of whether they would still be able to see satellite maps on their local news programs, and in terms of services which are provided by the Government based on the weather data, such as frost forecasts. Unfortunately, at about the same time as the Government announced the transfer of the weather satellites, other changes in the Weather Service were made known, including the fact that certain services (such as frost forecasting) would subsequently have to be purchased from private weather services rather than provided free by the Government, and that some Weather Bureau stations would be closed. Although these actions are unrelated to the issue of transferring the satellites to the private sector, they were all linked together in the press and the public mind.

A third complication arose when it was revealed that the Department of Commerce official in charge of studying the satellite transfer issue had been approached by Comsat concerning future job opportunities, thus leading to at least the appearance of impropriety. [9]

Thus the issue of transferring Landsat to the private sector has become tangled with many other issues which will ultimately have to be sorted out by Congress before action takes place. In fact, language requiring congressional consultations on the transfer plan was placed in several pieces of legislation, including an emergency jobs bill and the fiscal year 1984 NASA authorization bill.

EXPENDABLE LAUNCH VEHICLES

Another area in which policy is expected soon is the commercialization of expendable launch vehicles (ELV's). These rockets are the type which have been used since the beginning of the space program, and include all launch vehicles other than the Space Shuttle. In the United States, four ELV's are in use: Delta, Atlas-Centaur, Titan, and Scout. The last is a very small vehicle capable

[9] Washington Post, April 15, 1983, pp. A1, 12.

of placing only small payloads into orbit and is not being proposed for commercial operation.

In the case of ELV's, one issue involves Government subsidies, specifically whether the companies that are commercializing the vehicles should be required to pay back the Government for sunk costs in R&D. These have been roughly estimated as $91 million for Delta, $600 million for Atlas-Centaur, [10] and $1 billion for Titan 34D. [11] One argument is that these costs should be paid back to the Government since the companies will now be making profits on Government-developed hardware, while the counterargument is that neither the Space Shuttle nor the European Space Agency's Ariane launch vehicle, with which these ELV's would compete for traffic, are expected to recover sunk costs in their pricing schemes, so the commerializers of the ELV's should also not be expected to recover those costs.

The companies that are proposing commercialization of existing ELV's or constructing new ones are identified in the appendix. Unless they plan to build their own launch facilities (only two, ARC Technologies and Space Services, have indicated such plans), they will have to make arrangements for lease or purchase of Government facilities. In the case of the existing ELV's, all the pads are owned by the Air Force, although NASA currently leases the launch pads for Delta and Atlas-Centaur from the Air Force and a private company could sublease through NASA. Also, range safety services must be acquired to ensure, for example, that if the launch vehicle deviates from course it can be safely destroyed. These services are currently provided by the Air Force.

Other areas in which private companies launching ELV's would have to coordinate with the Government include complying with treaties such as the 1967 Outer Space Treaty which states that governments are responsible for all launches from their territory, and the 1972 Convention on International Liability for Damage Caused by Space Objects, which makes governments responsible for compensation for damage resulting from satellite launches (see part II). Launches would also have to be approved by the Federal Aviation Administration (FAA) for clearing the airspace during a launch, and frequencies for transmitting commands to and/or recieving data back from launch vehicles must be assigned by the Federal Communications Commission (FCC).

Only one private launch has successfully taken place to date—the 1982 test launch of Space Services' Conestoga rocket. The procedures required to gain approval for that launch were time consuming, and have led to the introduction of legislation in Congress to ease the way for companies wishing to pursue such activities. The bill introduced in the House by Congressman Dan Akaka (H.R. 1011) would designate the Department of Commerce as lead agency, while the Senate bill introduced by Senator Ernest Hollings (S. 560) would give that role to the FAA.

---

[10] These costs were estimated by NASA and do not include the development of the Thor booster on which the Delta design is based, nor the Atlas vehicle from which the Atlas-Centaur combination developed. Telephone conversation, April 1983.

[11] DOD estimate. Telephone conversation, April 1983.

Suggestions have also been made that either the State Department or NASA serve that role—State Department because it is ultimately responsible for adherence to the treaties governing space activities, NASA because of its expertise. The problem with assigning responsibility to NASA is potential conflict of interest. NASA is in a dilemma with regard to the commercialization of ELV's because although it wants to promote space activities in the United States, it has developed the Space Shuttle, with which commercial ELV's would compete. The national policy is that once the Shuttle is fully operational, all Government utilization of ELV's will cease. It is difficult to establish a policy which on the one hand promotes broad opportunities for commercial space endeavors while not creating competition for NASA's own system.

A high volume of uses for the Shuttle must be found in order to ensure that it will meet its expected economies. Already NASA has had to change its pricing strategy just to maintain a competitive posture with regard to the Ariane launch vehicle developed by the European Space Agency (ESA). Instead of recouping full costs of the Shuttle, NASA will now charge only enough to recover operating expenses. The impact of a fleet of privately operated ELV's, while providing a boom for customers, could spell doom for the Shuttle.

The Government's policy to phase out ELV's is what led to the proposals to commercialize the ELV's, because the private sector senses that there will be a market both for the Shuttle and the existing type of launch services. An important factor in this argument is whether NASA will procure a fifth Space Shuttle orbiter, for that will partially determine how often the Shuttle will fly, and therefore how many payloads it can take into space. Without the fifth orbiter, the Shuttle may be overbooked and customers might be willing to switch to an ELV. Another factor is whether the Shuttle system will meet its expected launch rate of 24 launches per year with 4 orbiters, which would also affect the number of customers looking for alternative launch arrangements. Some might want to double book on an ELV as insurance against a potential catastrophic failure of one or more orbiters.

There are obstacles to commercial ELV operators, however. For example, the United States is no longer the only country offering space launch services. ESA is aggressively marketing its Ariane launch vehicle and planning improvements to make it even more versatile and capable. In addition, there are signs that the Soviet Union may start offering launches on a commercial basis.

Thus there is competition for ELV operators not only from the Shuttle, but from other countries. The Office of Management and Budget (OMB) denied NASA's request for funding to procure a fifth orbiter in fiscal year 1984 because it did not see a need for another orbiter to meet expected traffic demands, so it is unclear as to whether a market really exists for all these different types of launch services.

Another potential obstacle is national security considerations both in terms of what types of satellites can be launched without adversely impacting the interests of the United States, and possible restrictions on the export of launch vehicles or launch vehicle technology.

It should also be noted that two companies have financed or are financing the development of upper stages for use either with the Shuttle or with ELV's. McDonnell Douglas developed the payload assist module (PAM) for use either with its Delta or with the Shuttle at its own expense, and markets the stage commercially. Recently, NASA signed a cooperative agreement with Orbital Systems Corp. (OSC) to develop an upper stage with an intermediate range of capability called the transfer orbit stage (TOS). OSC will privately fund development of TOS, although NASA will provide technical oversight at no charge. Under the cooperative agreement, NASA has also promised not to develop a similar vehicle of its own, although this does not preclude development by another company. NASA had been planning to develop such a stage itself until OSC offered to fund the project. If OSC drops out for any reason, NASA has indicated that it will step in. [12]

MATERIALS PROCESSING IN SPACE

The single area in which most discussion is heard concerning commercial space opportunities, or the "industrialization" of space, is in materials processing in space (MPS). Although NASA has very limited experience with MPS (only about 8 hours worth of experiments were conducted during the Apollo and Skylab programs) there is hope that there may be major industrial opportunities in this area.

NASA has two types of agreements which it offers in terms of MPS experiments; there is no exchange of funds in either case. One is the joint endeavor agreement in which NASA and the sponsoring organization share data from an experiment in return for a free Shuttle launch. There are only two existing joint endeavor agreements on MPS. One is with McDonnell Douglas working with Johnson and Johnson on electrophoresis experiments; this experiment has flown on two Shuttle missions already. The second is with Microgravity Research Associates to develop a process for the production of semiconductor materials. Another joint endeavor agreement, with GTI Inc. for the development of a furnace for use in MPS, was terminated after 1 year because GTI saw no immediate market for the device.

The other type of agreement is a technical exchange agreement in which companies are allowed to use existing NASA facilities for MPS experiments in return for data from the experiments. These facilities include, for example, sounding rockets, drop-tubes, and aircraft which fly in hyperbolic curves to create a few seconds of zero-g. NASA currently has technical agreements with John Deere, Honeywell, Dupont, and Inco. In addition to the activities done in cooperation with NASA, some companies are pursuing MPS research on their own. These companies are identified in the appendix.

The major obstacles in the path of MPS include lack of knowledge about the products or processes that might be developed in space factories because so little experimental work has been done, and the lack of orbital facilities for companies who want to per-

[12] Telephone conversation with a NASA representative, April 1983.

form MPS experiments. These issues underscore the importance of the debate over the proper role of the Government versus the private sector in such endeavors. There is a feeling among the private sector that NASA should be provided with more funding to perform basic research needed to identify the directions in which a company could proceed in order to develop a profitmaking enterprise, but NASA's space science and applications budget has been sharply constrained in the past few years. Also, there is the problem of who should develop the hardware for MPS. For example, one company representative explained that GTI Inc.'s decision to terminate its agreement with NASA for development of a furnace for MPS has left them in a quandry because there is no furnace available at this time suitable for their experiments. They do not want to spend money to develop a furnace themselves, so the future of their MPS program is in doubt. The representative stated that it did not matter to his company whether it leased facilities from NASA or from a private company such as GTI, just so it did not have to be responsible for providing such hardware. [13] Without the GTI agreement, however, which was terminated for lack of a defined market, the question remains as to who will develop the hardware.

Other areas in which concerns have been expressed include patent law and protection of proprietary information. These issues are discussed in part II of this report.

SPACE SHUTTLE

Operation of the Space Shuttle

Who should operate the Space Shuttle once it is no longer in an R&D phase has been a question debated for many years—without resolution. Communications, weather, and remote sensing satellites have all been transferred out of NASA once they were operational, so the question has arisen as to whether the Shuttle, too, should be transferred to another Government agency, the private sector, or a quasi-governmental organization.

A discussion of the options available for commercial operation of the Shuttle is beyond the scope of this report. Consequently, only the major policy issues will be identified. The first concerns military payloads. Assuming that DOD would not want to be dependent upon a commercial company for launch services, one option is to have DOD operate the entire Shuttle fleet. A second option would be to give DOD its own fleet of Shuttles while having a separate fleet for commercial and civil space flights (called "blue" and "white" fleets respectively). Of course, DOD might be persuaded to buy launches from a commercial company as long as certain safeguards and contingencies were provided for.

If NASA were to retain operational responsibility, the issue arises as to whether its budget would be adequately augmented to provide for whatever changes the agency would have to make organizationally and in hiring personnel. The NASA budget has been constrained for many years already because of the investment in the Space Shuttle, and concern might arise as to the health of

[13] Telephone conversation with representative of John Deere, Co., April 1983.

other NASA activities if large sums continued to be required for the STS system.

It is commonly argued, however, that the Government simply is not good at marketing what it develops and, once operational, a system should be handed over to the private sector. If this is done, the issue of Government subsidies will arise, both in terms of whether or not a private company would be required to pay back the Government for some or all of the sunk costs in the Shuttle, and in terms of whether the Government would be willing to subsidize a company in order to ensure that it could price Shuttle launches competitively with other launch vehicle options, particularly foreign ones. On the other side of the question is what, if any, restrictions the Government might impose on pricing. For example, NASA currently does not permit McDonnell Douglas to charge more than 30 percent of the internal rate of return (IRR) for the payload assist module. [14] Similar strictures might be imposed on Shuttle pricing as well, possibly making such an enterprise less attractive to the private sector.

As in the case of remote sensing satellites, there is the issue of how much it might cost the Government to buy back into the Shuttle system if the private entity decided to terminate its involvement because it was not profitable.

Another issue is who would perform R&D associated with improving the Shuttle system. Proposals have already been made to develop an unmanned version of the Shuttle (called SRB–X) using the solid rocket boosters for a heavy lift capability, and other improvements are likely to be identified as experience with the vehicle grows. If the private sector takes over operation of the Shuttle, would it be responsible for improvements, or would the Government continue to fund such activity as it has with communications satellites?

Shuttle-related hardware opportunities

The Shuttle also presents other commercial opportunities. The Shuttle is often described as a space truck, hauling cargo back and forth into space. Long-term facilities, either unmanned platforms or manned space stations, may be built by the Government or by the private sector to augment the Shuttle. It is generally accepted that the private sector cannot afford a massive R&D investment such as that needed for a manned space station, although one company, Space Industries, is discussing with NASA the possibility of a joint development. There also has been one proposal for an unmanned platform. Called Leasecraft, the device would provide power and communications subsystems, as well as an orbital maneuvering capability if refueled in space, for factories and perhaps observatories. The proposal is being made by Fairchild Industries and is based on the multimission modular spacecraft it developed for NASA and which has been used for the Solar Maximum Mission and Landsat 4. In addition, two companies have shown interest in designing facilities for use in the Shuttle cargo bay (see appendix).

[14] Meeting with NASA representative, April 1983.

Other opportunities may also present themselves in areas such as providing in-orbit power supplies for the Shuttle to allow it to stay in orbit for extended periods of time, development of a reusable Space Tug, development of a teleoperator retrieval system, and so forth. Although these are areas in which industry expects (or at least hopes) that NASA will take the lead, if it does not, the private sector may wish to proceed itself.

Private purchase of a fifth Shuttle orbiter

A different kind of proposal related to the Space Shuttle is one by SpaceTran Inc. to purchase a fifth Shuttle orbiter for NASA in exchange for marketing rights to commercial and foreign payloads. The first informal proposal was submitted to NASA in the spring of 1982 and reportedly asked for exclusive marketing rights to all Shuttle commercial and foreign payloads. Following discussions with NASA, this apparently has been modified, but the details have not been released.

In early 1983, Federal Express agreed to purchase 20 percent of SpaceTran and the company is now reassessing its plans. Although SpaceTran was expected to resubmit a plan to NASA on March 1, 1983, none had been submitted at the time this report was prepared. (SpaceTran is also working with Martin Marietta on the commercialization of the Titan launch vehicle.)

The SpaceTran offer not only demonstrates interest from the private sector in the Shuttle system, but would save NASA approximately $1 billion if approved. Although OMB rejected NASA's request to purchase a fifth orbiter because it did not see a market for it in the projected Shuttle flight manifest over the next decade, apparently SpaceTran is confident that such a market exists.

Payload and Space Shuttle processing

Also associated with the Space Shuttle are plans for building processing facilities at Kennedy Space Center. At the present time, NASA processes the payloads for both the Shuttle and ELV's, but the NASA facility is overloaded. Astrotech International is now building a complementary facility near KSC and has arrangements with NASA to ensure that payloads processed there will meet NASA standards, although these arrangements are only in an exchange of letters, not through a formal mechanism such as a cooperative agreement or memorandum of understanding. [15] Hughes Aircraft also is actively considering construction of a payload processing facility near KSC in conjunction with a facility for satellite assembly. [16]

NASA is also getting close to choosing a company for its Shuttle processing contract (SPC) at KSC. This will involve onsite processing (preparation for launch) of the Shuttle itself rather than its payloads, and is expected to be a multimillion dollar contract over several years. The SPC will cover Shuttle processing both at KSC and at Vandenberg Air Force Base, which will be the west coast launch site for the Shuttle beginning in 1985. Currently, Shuttle processing is performed by several contractors that supply the

[15] Telephone conversation with Astrotech International representative, April 1983.
[16] Telephone conversation with Hughes representative, May 1983.

flight hardware (Rockwell International, Martin Marietta, and United Space Boosters, Inc.). The SPC would consolidate this activity. [17] This is not directly related to the issue of whether and how to commercialize the Shuttle, but is seen as a step in making the Shuttle ready for its operational era, whatever arrangements are ultimately chosen.

Policy Issues

Although each of the areas discussed above presents unique policy questions, there are also broad issues which affect more than one area. Some of these have been mentioned already, but this section will summarize them. Legal issues are discussed in part II of this report.

PROPER ROLE OF THE GOVERNMENT IN SPACE COMMERCIALIZATION

Subsidies/financing mechanisms

There are several different ways in which the Government might wish (or be expected) to subsidize commercial space ventures: Through guaranteeing purchase of certain amounts of data or numbers of vehicles such as upper stages; through direct subsidies to make a commercial venture competitive with foreign systems; through not requiring payback of sunk Government costs in a system; or through tax incentives.

In an era of tight budgets, Government subsidies are viewed with increasing concern, but they may be necessary if it is decided that transferring these systems to the private sector and/or maintaining U.S. competitiveness with foreign systems such as Ariane have an overriding importance. Many of the programs which are being considered as commercial prospects do not have defined markets, making them less attractive for private investment. Without guarantees that, at least, no money will be lost, the private sector simply may not be willing to get into the space business.

One alternative that has been discussed is the potential of establishing a Space Bank or Space Industrialization Corporation to provide venture capital/financing for commercial space endeavors. These proposals have been viewed as premature for the past several years, but might bear reexamination at this time. They might require Government funding initially, but are meant to be self-supporting eventually.

Related to this issue is how much it might cost the Government to buy back into a system that had been transferred to the private sector, but which was not profitable. Without subsidies to ensure financial success for a company, the Government might end up, for example, without remote sensing data or access to appropriate upper stages. In some cases, the only alternatives might be to purchase the data or hardware from other countries, or to reinstate Government ownership of the system. Thus, the advantages of commercialization must be weighed against the potential failure of a commercial endeavor and resulting costs to the Government.

---

[17] Proposals Requested for Shuttle Processing Contract. NASA Press Release 83-3. Jan. 20, 1983.

Federal role in research and development

The issue of what role the Government should play in research and development vis-a-vis the private sector has been debated for many years. In the space business, this has been particularly visible in the case of advanced communications satellites R&D. NASA performed such R&D long after commercial communications satellites were available, but in 1973 the NASA program was terminated on the basis that the private sector should bear responsibility for advanced R&D. The private sector did not pick up the challenge, because they said it was too expensive, and NASA reentered the field in 1979. During that time, however, foreign countries such as France and Japan forged ahead in the technology.

With increasing space commercialization, the issue of who should perform both basic and advanced R&D will take on greater import. If systems such as the Space Shuttle, remote sensing satellites, and MPS are to continue to evolve, the Government may have to provide funding if the private sector is unwilling or unable to fund the R&D.

In the case of MPS, for example, the basic R&D must be done before a company can identify profitable directions to pursue. NASA has developed mechanisms such as joint endeavor agreements to encourage private sector participation in MPS, but no funding is provided and the experiments can prove prohibitively expensive for an interested company. It may be necessary to increase support for initial R&D funded by the Government if commercial activity is deemed important. A related issue is development of hardware needed for experimentation. Companies that might be willing to pay for an MPS experiment might not be willing or able to develop their own facilities, such as furnaces, which are not now available from NASA or private companies. A joint endeavor agreement between NASA and GTI Inc. for development of a furnace was terminated for lack of an identifiable market. Who then will develop such devices?

If the Government performs the R&D, another aspect of the issue is the relationship between the Government and the private sector in establishing what research should be done. NASA has been criticized in the past for performing R&D without adequate user input; steps might be taken to ensure maximum user involvement from the beginning.

Maintaining U.S. competitiveness with other countries

Both of the above issues are related to the question of how the United States can remain technologically competitive with other countries. This has been the subject of growing concern in the past few years, and one of the areas in which the United States has lost or is losing its lead is communications satellites.

The close relationship between Government and industry in foreign countries, unlike the separation between the two in the United States, is often viewed as creating unfair competition for U.S. goods and services. In the case of Ariane, for example, ESA has made it clear that it will subsidize that launch vehicle to whatever extent is necessary to make it competitive with the Space Shuttle. NASA is much more limited in what it can do to subsidize

the Space Shuttle without specific direction from the administration and Congress.

The 1958 National Aeronautics and Space Act states that the United States will remain a leader in world space activites, a theme echoed by recent administrations. If this truly is a major policy goal, then subsidies and Government sponsored R&D may be the sine qua non for maintaining that leadership.

Government fostering competition with itself

Apart from the question of U.S. competition with other countries is the question of how the Government can support commercial space endeavors without creating adverse competition for its own systems. A case in point is the commercialization of ELV's at the same time NASA is trying to prove the economies of the Space Shuttle system. This obviously creates quite a dilemma for NASA, which on the one hand is trying to encourage private sector interest in space, but on the other wants at least to break even on the Shuttle system. Statements from NASA officials show optimism that the Shuttle will prove itself in terms of economics as well as reliability, and the commercial ELV's will not seriously impact Shuttle business. Whether this is true or not remains to be seen. The question is whether NASA should actively encourage ELV commercialization, or simply endure it.

A related issue is what price controls NASA can impose on private sector operators and whether it could thereby unfairly affect the commercial attractiveness of ELV's. For example, NASA currently does not allow McDonnell Douglas to charge more than 30 percent of the internal rate of return on the PAM upper stages, and similar constraints might be placed on other systems.

NASA organization

An important aspect of the commercialization process is how NASA itself is organized to handle commercial proposals and how it communicates commercial opportunities to the private sector.

As described in the appendix, NASA has three different mechanisms for encouraging commercial space endeavors, but it is difficult to determine the differences between the three, what types of activities require what (if any) types of agreements in addition to those mechanisms (such as memoranda of understanding), and the status of various undertakings. Thus, it is difficult to determine the effectiveness of these mechanisms for promoting commercialization. Attention might be paid to the centralization of responsibility for these activities.

Another problem is how NASA educates the private sector about potential opportunities. For example, a criticism has been raised that NASA personnel involved in MPS research rarely give papers at technical meetings attended by scientists from the private sector who might benefit from that knowledge. Private meetings between specific companies and NASA representatives are hindered by limits on NASA's travel budget and restrictions on what the private sector is allowed to pay for without creating the appearance of impropriety between Government and industry. At the same time, NASA's budget for technology transfer and utilization activities is being cut. Mechanisms for better educating the private sector must

be developed if a commitment to commercialization of space is made.

Fifth orbiter/advanced in-orbit space facilities

Another factor which may impact on the commercialization of space is the availability of an adequate space transportation system and in-orbit space facilities, such as space stations or platforms, to support commercial activities.

One part of this concerns the debate over whether or not to procure a fifth orbiter. Although NASA and OMB agree that there is currently no requirement for a fifth orbiter, NASA is more optimistic that such a need will develop once the full potential of the space environment is realized. The question is whether the need will arise if there is no commitment to a fifth orbiter. A similar question arises with respect to space facilities, manned or unmanned, which would be needed for a full scale commercial enterprise.

Without commitments to these sorts of activities, a private company might not be willing to make the initial investment in research which would lead to future commercial activities, since there would be no guarantee that it could make use of whatever knowledge it gained.

Regulatory Issues

Regulatory issues are likely to arise as various space activities become more commercialized. At the present time, ELV's can serve as an example of some of the considerations that must be taken into account.

Types of satellites to be launched

Restrictions may have to be placed on the types of satellites that can be launched by the private sector. It is assumed that space systems with aggressive missions, such as antisatellite devices, would not be launched by a private company. But what if another country wanted to launch a military reconnaissance satellite? Or a navigation satellite intended primarily for civil use, but which could be diverted to military uses in times of crisis? Would such a launch be prohibited? Would it only be prohibited if it took place from U.S. soil, or could a company sell its launch vehicle to another country for launch from another site?

Similarly, how will restrictions on the resolution of remote sensing satellites be enforced for private operators (currently, the Government does not permit remote sensing satellites to have better than 10 meter resolution)? Will these restrictions apply to satellites constructed by other countries but launched by U.S. firms?

Regulations concerning export of launch vehicles/technology

Will private firms be allowed to export launch vehicles for launch from another country's launch site? This is important not only in terms of what type of satellite could be launched as noted above, but what the launch vehicle itself might be used for. Most launch vehicles (including Delta, Atlas, and Titan) were developed from military IRBM or ICBM technology. Assurances might have to be gained from the receiving country that they would not be

placed back into military service, as was done when Japan was allowed to manufacture Delta launch vehicles under license from McDonnell Douglas. With the growing awareness of the "giveaway" of U.S. technology to other countries, concerns might also be raised about how the launch vehicle technology might be used.

Lead agency identification

There are many other regulations concerning ELV's that will have to be dealt with, including assurances that launches will not violate treaties to which the U.S. is a signatory, the use of radio frequencies, clearing airspace around the launch site, and so forth. These have already been widely discussed in congressional hearings and the trade press. Legislation has been introduced in the House and Senate concerning designation of a lead agency as the point of contact for private firms wishing to engage in commercial ELV activity. Ostensibly this would ease the way for the private sector, making such endeavors more attractive, and might also serve the Government's interest in terms of coordinating procedures.

If a lead agency is designated, the question arises of which agency it should be. Four agencies have been mentioned: The Department of Commerce, the Department of Transportation (specifically the FAA), the Department of State, and NASA itself. The House bill (H.R. 1011) recommends the Department of Commerce since it is sensitive to the needs of the private sector, while the Senate bill (S. 560) recommends FAA since it has experience in the related area of aeronautics. Department of State has been suggested (so far informally) perhaps because it is ultimately in charge of adherence to treaty obligations, and NASA has been mentioned because of its obvious expertise in the space launch business, although it might have a conflict of interest since commercial ELV's would be competing with its Space Shuttle. One suggestion has been to name NASA as an interim contact point, while deferring a decision on what agency should serve as the lead.

Role of State and local governments

The above issues discuss possible regulations by the Federal Government, but State and local governments may also have a role to play, especially if new launch sites are established within their borders. For example, Space Services Inc. launched the Conestoga rocket from Texas and there has been some discussion of establishing a launch site in Hawaii. What role the State and local governments should play will need to be determined in the near future, particularly with regard to coordination with the Federal Government.

Monopolies

A major issue during consideration of the 1962 Communications Satellite Act was how to prevent a monopoly from developing in the area of providing satellite communications services. Similar concerns will likely develop in the commercialization of other space technologies, and have, in fact, already been raised in connection with the land and weather satellites, and ELV's.

21

National Security

National security issues are also likely to impact on commercialization decisions such as who should operate the Space Shuttle, access to commercial ELV's by DOD in times of crisis, access to privately owned launch sites in times of crisis, resolution limits on remote sensing satellites, use of commercial ELV's by foreign governments, and technology transfer in general (including, for example, building ground stations in foreign countries for receiving data from U.S. commercial satellites such as those proposed by American Science and Technology for remote sensing). One question is what agency should be responsible for ensuring that national security issues are resolved. DOD would seem a natural choice, but also might be viewed by the private sector as placing too many constraints on operations, so a more neutral agency, perhaps one of those being considered for lead agency responsibility for ELV's, might be designated instead.

Conclusion

The field of space commercialization is expanding rapidly. Many companies are showing interest in commercial space activities ranging from expendable launch vehicles to remote sensing satellites to materials processing in space.

President Reagan's 1982 space policy states that commercial space endeavors are to be encouraged as long as they are consistent with national security, but many policy issues remain to be resolved. The expeditious resolution to these many issues is needed if commercialization is to proceed full pace, but their complexity makes such quick action unlikely. In the meantime, consideration might be given to providing NASA with direction and funding required to centralize its activities related to commercialization and to perform necessary research and development to provide a sound basis upon which the private sector can make decisions about investing in space. Additional NASA resources may be needed for educational functions to increase the awareness of private companies as to what opportunities already exist.

PART II: THE COMMERCIALIZATION OF SPACE TECHNOLOGIES: SOME PRESENT AND FUTURE LEGAL ISSUES

Prepared by Daniel Hill Zafren, Specialist in American Public Law, American Law Division, Congressional Research Service.

INTRODUCTION

An attempt is made here to discuss and analyze some of the diverse and complex aspects of legal control that are or may deserve consideration in the commercialization of space technologies, that is, in the transition of Government owned and operated civilian space activities to strictly private ownership and operation, or civilian space activities originating through private initiative. By necessity, this overview must in large part be general in nature. A more particular assessment would have to be premised on the specific facts and circumstances surrounding any such actual transfers or ventures. Such items as the type and scope of the activity, the location of its inception and operation, and the nature of the entities participating, may be of special relevance. Positions and viewpoints of participants, existing and potential competitors, consumers and users, governmental agencies, international organizations, or other nations, might be germane to legal considerations or determinations.

Thus, the present and future legal issues raised here require an international law as well as a domestic regulatory diagnosis. This entails a narrow circumspection based on the particular space activity involved, and a broader evaluation covering regulations or controls over business activity and technological development in general.

INTERNATIONAL LEGAL RESPONSIBILITY AND LIABILITY

No matter what the form and content of the arrangement for the United States to domestically shift the ownership and control of its space activities, any such unilateral act would appear to be without international legal effect. Thus, it would be the United States itself that would be held accountable under treaty law and customary international law for the obligations and responsibilities concerning such activities or even "pure" private activities. Internationally, such a transfer would appear to place the United States in a theoretical dichotomy. It will have given certain direct rights and privileges it has enjoyed under international law to the private commercial interests of its citizenry while still being primarily liable for a wide array of adverse effects that might emanate from the exercise of those rights. Since Article 6, Cl. 2 of the Constitution of the United States makes treaties the supreme law of the United States, U.S. citizens would be bound as a matter of domestic law by the self-executing provisions of space treaties in exercising actions or

activities covered thereby, and the authority settled upon by the United States governing any transfer might expressly provide for actual fulfillment of international requirements. However, such would not displace the United States as an actual obligor under international law.

SPACE LAW TREATIES

Four major multilateral treaties, drafted and signed under United Nations auspices, comprise the corpus of space law today. The so-called Outer Space Treaty [1] is the most fundamental agreement, and the one upon which the later treaties were elaborated or expanded upon. Probably the most germane provision for the purposes of the discussion here is that portion of Article VI which reads:

ARTICLE VI

> States Parties to the Treaty shall bear international responsibility for national activities in outer space, including the moon and other celestial bodies, whether such activities are carried on by governmental agencies or by nongovernmental entities, and for assuring that national activities are carried out in conformity with the provisions set forth in the present Treaty. The activities of nongovernmental entities in outer space, including the moon and other celestial bodies, shall require authorization and continuing supervision by the appropriate State Party to the Treaty.

Importantly, this provision makes no distinction between activities carried out by the State itself or by its private commercial enterprises. Thus, it would be applicable to all space activities, such as telecommunication satellite activities. "Therefore, as opposed to the traditional rule in telecommunications, States are responsible for outer space activities carried out by any of their private nationals and firms, even if the State does not exercise any direct or indirect control over such activities. Indeed, failure to undertake this responsibility would constitute a breach of the principle of control and supervision over non-governmental entities as stated in the second sentence. . ." [2]

Some other basic obligations and responsibilities can be found in the Outer Space Treaty. The premise for international liability for damage is set forth in Article VII:

ARTICLE VII

> Each State Party to the Treaty that launches or procures the launching of an object into outer space, including the moon and other celestial bodies, and each State Party from whose territory or facility an object is launched, is in-

---

[1] Treaty of Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies, January 27, 1967[1967], 18 U.S.T. 2410, T.I.A.S. 6347

[2] N.M. Matte, *Aerospace Law-Telecommunications Satellites* (1982), at 81.

ternationally liable for damage to another State Party to the Treaty or to its natural or juridical persons by such object or its component parts on the Earth, in air space or in outer space, including the moon and other celestial bodies.

Retention of jurisdiction and control over objects in outer space is covered by Article VIII:

ARTICLE VIII

A State Party to the Treaty on whose registry an object launched into outer space is carried shall retain jurisdiction and control over such object, and over any personnel thereof, while in outer space or on a celestial body. Ownership of objects launched into outer space, including objects landed or constructed on a celestial body, and of their component parts, is not affected by their presence in outer space or on a celestial body or by their return to the Earth. Such objects or component parts found beyond the limits of the State Party to the Treaty on whose registry they are carried shall be returned to that State Party, which shall, upon request, furnish identifying data prior to their return.

Some of the other obligations contained in this Treaty are: carrying on activities in accordance with international law (Article III); avoidance of contamination; avoidance of adverse changes in the environment of the Earth from the introduction of extraterrestrial matter; and international consultations in certain instances before proceeding with activities or experiments. There is, of course, room for great variation in interpretation of these or other prescriptions, as well as to whom, and to what extent they would actually apply. [3]

The so-called Astronaut Assistance and Return Agreement [4] elaborates on the general provisions of the Outer Space Treaty dealing with assistance to be given to astronauts, and provides for such matters as notification of accidents, and the rescue and return of spacecraft personnel and space objects. "Launching authority" as used in this treaty refers to the State "responsible" for launching (Article VI). A number of potential legal problems that might need addressing can be envisioned. For example, if there is a launching of a space object by private U.S. industry that falls within the territory of another Party to the Treaty, that Party's responsibility is to notify the launching State (the United States), and if requested by it and with its assistance to recover the object or its component parts and at the launching State's expense. What kind of obligation, including items such as timing, form and content, as regards sending or receiving such notifications would or should

[3] Added uncertainity can be found concerning the pending so-called Moon Treaty. See. e.g., Congressional Research Service, Senate Committee on Commerce, Science, and Transportation, 96th Cong., 2d Sess. *Agreement Governing the Activities of States on the Moon and Other Celestial Bodies*, Part 4 (Committee Print 1980).

[4] Agreement on the Rescue of Astronauts, the Return of Astronauts, and the Return of Objects Launched into Outer Space, April 22, 1968 [1969], 19 U.S.T. 7570, T.I.A.S. No. 6599.

exist between the U.S. Government and the involved private industry? To what extent would or should each participate in the decision to request a return, the kind and participation of assistance, and the bearing of expenses? Additional legal complexities can be speculated on if the object lands in a nation not Party to the Treaty.

The so-called Outer Space Liability Convention [5] establishes the rule of absolute liability for a launching State for losses suffered by persons (other than its nationals) and property from reentering space objects and their components. Even though this Treaty has been the subject of criticism as being legally inadequate to govern many liability questions concerning space activities, [6] since a launching State is defined therein as including a State from whose territory or facility a space object is launched, the United States has a potential absolute and unlimited liability for deaths, injury or damage caused by space objects (or their parts) launched by its nationals from within its territory or from a facility of the United States (even if on the high seas). A resolution of how such liability should be affixed in such instances, including the manner in which claims are to be handled, would appear to be a major prerequisite for any domestic scheme to promote private space activities or any arrangement of transferring present Government operations or activities in space to the private sector.

The so-called Registration Convention, [7] requires a launching State (again defined as including a State from whose territory or facility a space object is launched) to enter each launching in an appropriate registry with certain information to be furnished to the Secretary General of the United Nations. The division/responsibility concerning such functions would also seem to be a matter for domestic operational agreement.

SOME OTHER TREATIES

A number of additional multilateral agreements to which the United States is a Party may be germane with respect to any particular kind of privately run activity, or possibly problematical with the U.S. (or its representative) membership in certain international organizations, or possibly contrary to or inconsistent with the rules set up thereunder. For example, Intelsat, the International Telecommunications Satellite [8] Organization, is an organization established for the purpose of continuing and carrying forward on a definitive basis, the design, development, construction, establishment, operation and maintenance of the space segment of the global commercial telecommunications satellite system. Recently, an application filed by a private corporation with the FCC seeking permission to build and launch two satellites over the Atlantic to

[8] Agreement Relating to the International Telecommunications Satellite Organization (Intelsat), August 20, 1972 [1973], 23 U.S.T. 3813. Also, see, Operating Agreement Relating to the International Telecommunications Satellite Organization (Intelsat), August 20, 1971 [1973], 23 U.S.T. 4091.

provide transponders for multinational corporations, video networks and other entities wanting their own private network between the United States and Europe, has brought an outcry from an Intelsat official that a private Atlantic satellite network would threaten the integrity of Intelsat's global system and would be in violation of the Intelsat treaties.[9] Inmarsat, the International Maritime Satellite Organization,[10] is similar to Intelsat but is an international organization which provides the space segment for maritime satellite communications. Interestingly, both organizations allow a signatory to the operating arrangements to be a private entity, such as Comsat. If other private entities become involved with activities whereby it may be competitively necessary to receive information from Comsat as such a signatory, some legal prescription to that effect may be necessary.[11] Another example of potential conflict of roles the U.S. Government might be required to perform under international commitment and one that might emerge as in the best interests of an activity taken over by private industry could surface if weather satellites are sold to such private interests. The United States as a party to the Convention of the World Meteorological Organization[12] is a member of the international organization, the purpose of which are:

PURPOSES

The purposes of the Organization shall be

(a) To facilitate worldwide cooperation in the establishment of networks of stations for the making of meteorological observations or other geophysical observations related to meteorology and to promote the establishment and maintenance of meteorological centers charged with the provision of meteorological services;

(b) To promote the establishment and maintenance of systems for the rapid exchange of weather information;

(c) To promote standardization of meteorological observations and to ensure the uniform publication of observations and statistics;

(d) To further the application of meteorology to aviation, shipping, agriculture, and other human activities; and

(e) To encourage research and training in meteorology and to assist in coordinating the international aspects of such research and training.

CUSTOMARY INTERNATIONAL LAW

Even in the absence of any of the treaties discussed above, there has been a continuous flow of international decisions and practices to support the international principle of liability of a nation concerning acts carried out in its own territory that have an adverse

[9] *The Washington Post*, March 31, 1983.

affect on the territory of another nation. [13] While this is not a fully settled point in international law, it would seem that an instance in which an activity instigated within a nation's territory and which is intended to be carried out over the territory of another nation, even if that first nation is legally entitled to do so, bolsters the possible application of this principle in the event of adverse consequences to that other nation's territory.

SOME UNRESOLVED INTERNATIONAL LEGAL PROBLEMS

If private industry supplants the Government in the conduct of certain space operations, the private sector could become more directly embroiled in a number of outstanding international controversies. It might well necessitate coordinating legal and foreign policy positions vis-a-vis the Government. Points of dissention exist with respect to the legal nature of the space environment itself or portions of it, national rights with reference thereto, and/or particular activities themselves either in their space contact or their effects on the Earth. Further complication is found in an intermeshing of many of these elements. Perhaps, much of the legal controversy can be attributed to the developed/developing nations dichotomy.

The delimitation of outer space

"The problem of whether and how to define outer space, particularly where to draw its lower limit and thus to distinguish it from airspace, belongs, without any doubt, to the oldest and most discussed questions of the law of outer space and its doctrine." [14] At the crux of this issue is the fact that different legal regimes and rights exist for airspace and outer space. Airspace is subject to the sovereign claim of the territory above it; outer space is not subject to any claim of sovereignty. Without a certain demarcation between these two regimes various degrees of legal uncertainty are raised, particularly as to activities that occur in both spheres. For example, in spite of administrative interpretation that the Space Shuttle is not an aircraft, there is an expression of opinion by some legal commentators that as a matter of law the Space Shuttle must be considered an aircraft while functioning in navigable airspace. [15]

The geostationary orbit

Closely related to the demarcation issue is the problem of the geostationary orbit—the equatorial orbit at which a satellite takes 24 hours to circle the Earth so that it is stationary as viewed from Earth, at an altitude of approximately 36,000 km. [16] Claims have been advanced to rights of sovereignty over certain segments of the geostationary orbit, and thereby a limited area of outer space, in

---

[16] Office of Technology Assessment, *Solar Power Satellites* (OTA-E-144, August 1981), at 296 (Glossary).

favor of individual states located below such segments. The so-called Bogota Declaration [17] states in part: "There is no definition of outer space that is valid and satisfactory for the international community such as might be cited to support the argument that the geostationary orbit is included in outer space." The equatorial States basically use the stance represented by the New International Economic Order to substantiate their claim of sovereignty to such orbit as a natural resource. [18] The United States has, of course, rejected such a claim on scientific and legal grounds. [19] Yet, this legal issue subsists, accentuated by the practical reality that by far most communications satellites are those stationed in such orbit. [20]

Direct television broadcasting

The international community has not yet been able to formulate an international agreement on direct television broadcasting (whereby a broadcast goes from the satellite into a home receiver without any intervening relay action). The international issue here is open dissemination of ideas and information. Some States regard it as potentially introducing repugnant ideas into their territory. "The free transmission and reception of information is perceived differently in States possessing differing degrees of development and different ideological motivations." [21] The latest principles (which are not binding) can be found in an Annex to a General Assembly Resolution adopted in December 1982:

A. PURPOSES AND OBJECTIVES

1. Activities in the field of international direct television broadcasting by satellite should be carried out in a manner compatible with the sovereign rights of states, including the principle of nonintervention as well as with the right of everyone to seek, receive and impart information and ideas as enshrined in the relevent United Nations instruments.

2. Such activities should promote the free dissemination and mutual exchange of information and knowledge in cultural and scientific fields, assist in educational, social and economic development, particularly in the developing countries, enhance the qualities of life of all peoples and provide recreation with due respect to the political and cultural integrity of states.

3. These activities should accordingly be carried out in a manner compatible with the development of mutual understanding and the strengthening of friendly relations and cooperation among all states and peoples in the interest of maintaining international peace and security.

B. APPLICABILITY OF INTERNATIONAL LAW

4. Activities in the field of international direct television broadcasting by satellite should be conducted in accordance with international law, including the Charter of the United Nations, the Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies, of 27 January 1967, the relevant provisions of the International Telecommu-

[21] C.Q. Christol, *The Modern International Law of Outer Space* (1982), at 607.

nication Convention and its Radio Regulations and of international instruments relating to friendly relations and cooperation among states and to human rights.

C. RIGHTS AND BENEFITS

5. Every State has an equal right to conduct activities in the field of international direct television broadcasting by satellite and to authorize such activities by persons and entities under its jurisdiction. All states and peoples are entitled to and should enjoy the benefits from such activities. Access to the technology in this field should be available to all states without discrimination on terms mutually agreed by all concerned.

D. INTERNATIONAL COOPERATION

6. Activities in the field of international direct television broadcasting bv satellite should be based upon and encourage international cooperation. Such cooperation should be the subject of appropriate arrangements. Special consideration should be given to the needs of the developing countries in the use of international direct television broadcasting by satellite for the purpose of accelerating their national development.

E. PEACEFUL SETTLEMENT OF DISPUTES

7. Any international dispute that may arise from activities covered by these principles should be setttled through established procedures for the peaceful settlement of disputes agreed upon by the parties to the dispute in accordance with the provisions of the Charter of the United Nations.

F. STATE RESPONSIBILITY

8. States should bear international responsibility for activities in the field of internatinal direct television broadcasting by satellite carried out by them or under their jurisdiction and for the conformity of any such activities with the principles set forth in this document.

9. When international direct television broadcasting by satellite is carried out by an international intergovernmental organization, the responsibility referred to in Paragraph 8 above should be borne both by that organization and by the states participating in it.

G. DUTY AND RIGHT TO CONSULT

10. Any broadcasting or receiving state within an international direct television broadcasting satellite service established between them requsted to do so by any other broadcasting or receiving state within the same service should promptly enter into consultations with the requesting state regarding its activities in the field of internatinal direct television broadcasting by satellite, without prejudice to other consultations which these states may undertake with any other state on that subject.

H. COPYRIGHT AND NEIGHBORING RIGHTS

11. Without prejudice to the relevant provisions of international law, states should cooperate on a bilateral and multilateral basis for protection of copyright and neighboring rights by means of appropriate aggreements between the interested states or the competent legal entities acting under their jurisdiction. In such cooperation they should give special consideration to the interests of developing countries in the use of direct television broadcasting for the purpose of accelerating their national development.

I. NOTIFICATION TO THE UNITED NATIONS

12. In order to promote international cooperation in the peaceful exploration and use of outer space, states conducting or authorizing activities in the field of international direct television broadcasting by satellite should inform the Secretary General of the United Nations, to the greatest extent possible, of the nature of such activities. On receiving this information the Secretary General should disseminate it im-

mediately and effectively to the relevant specialized agencies as well as to the public and the internationl scientific community.

J. CONSULTATIONS AND AGREEMENTS BETWEEN STATES

13. A state which intends to establish or authorize the establisment of an international direct television broadcasting satellite service shall without delay notify the proposed receiving state or states of such intention and shall promptly enter into consultation with any of those states which so requests.

14. An international direct television broadcasting satellite service shall only be established after the conditions set forth in paragraph 13 above have been met and on the basis of agreements and/or arrangements in conformity with the relevant instruments of the International Telecommunication Union and in accordance with these principles.

15. With respect to the unavoidable overspill of the radiation of the satellite signal, the relevant instruments of the International Telecommunication Union shall be exclusively appplicable.

Remote sensing

There has also been a failure internationally to agree on principles governing remote sensing (observing conditions on the Earth from a satellite), or even to agree on a working definition thereof. Basically, the dispute involved is the position of the sensed States (which, it seems, tend to usually be complaining developing nations) that there be some form of prior consent and that they have some rights concerning the information obtained and how it is distributed. [22]

Use of nuclear power sources

The use of nuclear power sources in outer space is another object of legal dispute, particularly on the safety and environmental concerns. While covered to some extent by the existing space treaties, a new agreement in the form of supplementation on areas as consultation, notification, emergency assistance, and liability and recovery of damages is yet to be agreed on. [23]

Common heritage of mankind

The developing nations believe that the provision in Article I of the Outer Space Treaty that outer space "shall be the province of mankind" articulates the "common heritage of mankind" concept. [24] Additional support is gleaned from the specific provision in the recently proposed Moon Treaty providing that the natural resources of the Moon "are the common heritage of mankind," and the recently advanced Law of the Sea Treaty declaring the area and its resources as the common heritage of mankind. [25] "The common heritage of mankind doctrine applies to the use of space by the placement of a craft in a specific location." [26]

---

[22] Id., at 732–733.

[25] Art. 136; 21 I.L.M. 1293 (1982).

[26] Tennan, *Outer Space: A Preserve for All Mankind*, 2 H. J. Int'l L. 145, 153 (1979)

> For developing countries, "common heritage" means common ownership of the resources and majority control over their disposition. This translates into insistence that no single country, or entity under its control, has the independent right to use the commonly owned resource. Access to the resources must first be approved by the international community on the basis of one nation-one vote. As a result, the developing countries would collectively control who is allowed to exploit and use the resource. The concept of the "common heritage of mankind" does not, in the view of the Third World, recognize that industrialized countries with space technology should have a greater voice in regulating outer space resource technology. [27]

In spite of a contrary legal posture by the United States and most legal commentators that the common heritage concept does not amount to an international legal doctrine, and which has no fixed meaning or binding effect, it does, at least, arguably raise some degree of apprehension on the certainty or recognition of the legal effects attached or attachable to acts or activities in outer space.

Present Domestic Regulatory Schemes

U.S. statutes and regulations that may be applicable to private activity in or concerning outer space are numerous and complex. A theoretical examination may be misleading because the application of each or any of them, in whole or in part, would depend on the numerous factors involved in an actual situation. There does not seem to be any existing strictly designed framework which either specifically disallows or fosters "pure" private commercialization of space or space activity. Congress, in the statutory creation of Comsat, a nongovernmental, forprofit corporation, to act for the United States in establishing and participating in an international, commercial communications satellite system, has expressly reserved the right to repeal, alter or amend this enabling legislation at any time, [28] besides providing for such things as the powers of the corporation [29] and annual reporting to the Congress on its activities and accomplishments. [30]

An attempt will be made here to point out some areas of regulation which appear to be adverse to or an encouragement of either private commercial actions in some specifically related activity or in general. Seemingly, more of these provisions appear to be of an adverse nature, but this does not necessarily mean that such private endeavors would be less legally feasible than other kinds of private commercial undertakings, or that the private bar could not meet the challenge of accomplishing an intended effect despite such adversity.

[30] 47 U.S.C. §744.

33

FEDERAL DOMINANCE

The legal question to be addressed here is whether by virtue of the National Aeronautics and Space Act of 1958, [31] any and all private space activity can only be carried out under the aegis of NASA? With respect to civilian space activity, the act provides in part that activities in space "shall be the responsibility of, and shall be directed by, a civilian agency exercising control over aeronautical and space activities sponsored by the United States..." [32] "Aeronautical and space activities" is defined as "(A) research into, and the solution of, problems of flight within and outside the Earth's atmosphere, (B) the development, construction, testing, and operation for research purposes of aeronautical and space vehicles, and (C) such other activities as may be required for the exploration of space. . . ." [33] One legal commentator has concluded that an activity such as private aerospace transportation would not be encompassed thereby because it would be operated for profit and not for research or exploration purposes, and that it is not "sponsored" by the United States. [34] Yet, it would seem that a strong argument can be made to support the position that all civilian space activity could fall within the purview of the act. First, the legislative history of the act appears to support a contention that the only activities excludable from potential coverage were those "aeronautical" activities in existence in 1958, and that exploitation activities as well as exploration ones are included. The conference report, in discussing definitions, states in part: "The purpose is to make clear that the act is concerned primarily with research, development, and exploration. The use of the word "activities" is intended to be broad in the area of outer space because no one can predict with certainty what future requirements may be. . . . These activities would include scientific discovery and research not directly related to travel in outer space but utilizing outer space, and the development of resources which may be discovered in outer space." [35] Second, sponsorship would arguably include other actions or situations than where there is Federal funding and substantial Federal supervision. The plain meaning includes "one who assumes responsibility for some other person or thing." [36] As previously discussed, the United States is internationally responsible for private space activity, and Congress has expressly declared responsibility for all activities in space in the act. [37]

Another area of Federal dominance appears to be NASA's authority to initiate and carry out a program of research, technology, monitoring, and other appropriate activities directed to understanding the physics and chemistry of the upper atmosphere. [38]

[37] 42 U.S.C. §2451 (b)
[38] 42 U.S.C. §2483 (b)

NASA has taken a seemingly broader approach through "Joint Endeavor Agreements" a form of NASA/industry relationship to encourage private sector participation in certain research. [39]

MULTIPLE FEDERAL AGENCY JURISDICTION

Various, overlapping and perhaps conflicting jurisdiction over certain space activities may be exercised by a number of Federal administrative agencies. Private rocket launching is perhaps the prime example. The Federal Aviation Act of 1958 authorizes regulations to, inter alia, prevent collision between aircraft and airborne objects. [40] The FAA has promulgated the following with regard to operating limitations and notice requirements for unmanned rockets: [41]

§101.23 Operating limitations.

No person may operate an unmanned rocket—

(a) In a manner that creates a collision hazard with other aircraft;

(b) In controlled airspace;

(c) Within five miles of the boundary of any airport;

(d) At any altitude where clouds or obscuring phenomena of more than five-tenths coverage prevails;

(e) At any altitude where the horizontal visibility is less than five miles;

(f) Into any cloud;

(g) Within 1,500 feet of any person or property that is not associated with the operations; or

(h) Between sunset and sunrise.

(Sec. 6(c), Department of Transportation Act (49) U.S.C. 1655(c))

[Doc. No. 1580, 28 FR 6722, June 29, 1963, as amended by Amdt. 101-4, 39 FR 22252, June 21, 1974.]

§101.25 Notice requirements.

No person may operate an unmanned rocket unless, with 24 to 48 hours before beginning the operation, he gives the following information to the FAA ATC facility that is nearest the place of the intended operation:

(a) The names and addresses of the operators.

(b) The number of rockets to be operated.

(c) The size and weight of each rocket.

(d) The maximum altitude to which each rocket will be operated.

(e) The location of the operation.

(f) The date, time, and duration of the operation.

(g) Any other pertinent information requested by the ATC facility.

The Department of State might assert some jurisdiction based on its authority under the Arms Export Control Act [42] and its accompanying regulations concerning launch vehicles and rockets. [43] NASA could probably assert jurisdiction under the broad sweep of the National Aeronautics and Space Act, [44] particularly if NASA installations are used. [45] The FCC could probably assert jurisdic-

[40] 49 U.S.C. §1348 (c)

[41] Title 14, Code of Federal Regulations (CFR).

[42] 22 U.S.C. §2778.

[43] 22 CFR §121.01

[44] 42 U.S.C. §2451 et seq.

[45] 14 CFR, Part 1204, Subpart 10. If launching pads of the Air Force are involved, the Department of the Air Force may also be an interested agency.

tion by virtue of the communications frequencies required in a launching under its authority granted by the Federal Communications Act of 1934.[46] A "rocket" also falls within the definition of "destructive device" under the firearms provisions of the Criminal Code[47] and, therefore, some assertion of jurisdiction might be made by the Bureau of Alcohol, Tobacco and Firearms. If special taxes are involved, the Internal Revenue Service also might step in.

Besides this potential Federal governmental involvement, it is conceivable that some of the States might assert some jurisdiction if, for example, the launching takes place within that State or the private entity conducting the launching is organized under that State's laws, and the State(s) have relevant legislation such as dealing with rules of conduct for aeronautical and/or hazardous activities.[48] It is even possible that certain local laws and regulations might be applicable. Related activities could also be covered by a myriad of laws, for example, Federal, State, and local labor laws concerning the rocket launching personnel.

PATENTS

There appears to be a great deal of confusion concerning the rights to inventions which have significant utility in the conduct of space activities, particularly where some contract exists with NASA. At the very least, it would seem that a private entity would or might be subjected to a more protracted and cumbersome procedure in obtaining such a patent than with other commercial inventions. The pertinent provisions in section 305[49] of the National Aeronautics and Space Act of 1958 read as follows:

PATENT APPLICATION

(c) No patent may be issued to any applicant other than the Administrator for any invention which appears to the Commissioner of Patents to have significant utility in the conduct of aeronautical and space activities unless the applicant files with the Commissioner, with the application or within thirty days after request therefore by the Commissioner, a written statement executed under oath setting forth the full facts concerning the circumstances under which such invention was made and stating the relationship (if any) of such invention to the performance of any work under contract of the Administration. Copies of each such statement and the applications to which it relates shall be transmitted forthwith by the Commissioner to the Administrator.

ISSUANCE OF PATENT TO APPLICANT; REQUEST BY ADMINISTRATOR; NOTICE; HEARING; DETERMINATION; REVIEW

(d) Upon any application as to which any such statement has been transmitted to the Administrator, the Commissioner may, if the invention is patentable, issue a patent to the applicant unless the Administrator, within ninety days after receipt of such application and statement, requests that such patent be issued to him on behalf of the United States. If, within such time, the Administrator files such a request with the Commissioner, the Commissioner shall transmit notice thereof to the applicant, and shall issue such patent to the Administrator unless the applicant within thirty days after receipt of such notice requests a hearing before a Board of Patent Interferences on the question whether the Administrator is entitled under

this section to receive such patent. The Board may hear and determine, in accordance with rules and procedures established for interference cases, the question so presented, and its determination shall be subject to appeal by the applicant or by the Administrator to the Court of Customs and Patent Appeals in accordance with procedures governing appeals from decisions of the Board of Patent Interferences in other proceedings.

FALSE REPRESENTATIONS; REQUEST FOR TRANSFER OF TITLE TO PATENT; NOTICE; HEARING; DETERMINATION; REVIEW

(e) Whenever any patent has been issued to any applicant in conformity with subsection (d) of this section, and the Administrator thereafter has reason to believe that the statement filed by the applicant in connection therewith contained any false representation of any material fact, the Administrator within five years after the date of issuance of such patent may file with the Commissioner a request for the transfer to the Administrator of title to such patent on the records of the Commissioner. Notice of any such request shall be transmitted by the Commissioner to the owner of record of such patent, and title to such patent shall be so transferred to the Administrator unless within thirty days after receipt of such notice such owner of record requests a hearing before a Board of Patent Interferences on the question whether any such false representation was contained in such statement. Such question shall be heard and determined, and determination thereof shall be subject to review, in the manner prescribed by subsection (d) of this section for questions arising thereunder. No request made by the Administrator under this subsection for the transfer of title to any patent, and no prosecution for the violation of any criminal statute, shall be barred by any failure of the Administrator to make a request under subsection (d) of this section for the issuance of such patent to him, or by any notice previously given by the Administrator stating that he had no objection to the issuance of such patent to the applicant therefor.

The courts have held that when an invention is developed under contract with NASA and subsequently reduced to practice outside the contract, the invention can be considered to have been made as a result of the contract. [50] "Contract" is broadly defined as including "any actual or proposed contract, agreement, understanding, or other arrangement, and includes any assignment, substitution of parties, or subcontract executed or entered into thereunder. . . ." [51] However, it appears that NASA has taken a restrictive view of this provision and not all actions which literally might fall within it have been so included, for example, joint endeavors, in order to maintain private incentive and initiative. [52]

COMSAT

Comsat was created as a private corporation "subject to appropriate Government regulation" as the U.S. participant in a global communications satellite system, with such entity to be the U.S. representative in Intelsat and Inmarset. [53] The existence of this private commercial entity has at least two possible legal inhibitions to the entry of other commercial endeavors either using such communication services or perhaps dependent on the inner workings of these two international organizations. The enabling act provides: "It is not the intent of Congress by this act to preclude the use of the communications satellite system for domestic communication services where consistent with the provisons of this act nor to pre-

[50] *Hummer* v. *Administrator of the National Aeronautics and Space Administration* 500 F.2d 1383, 1388 (Cust. & Pat. App. 1974).

[51] 42 U.S.C. §2457(j)(2).

[52] See NASA Memo of June 19, 1979 from Assistant General Counsel for Patent Matters to General Counsel on "Applicability of Section 305 of the Space Act to Joint Endeavors." Such is actually incorporated in the Joint Endeavor Agreements.

[53] 47 U.S.C. §701 et seq.

clude the creation of additional communications satellite systems, if required to meet unique governmental needs or it is otherwise required in the national interest." [54] Thus, it would seem that for a private commercial entity to use the system for domestic communications services in addition to compliance with general provisions of law it would be confined to activities "consistent" with this act. To establish an additional communications system, a potential entrant would have to show that such is required to meet unique governmental needs or in the national interest. Further, by virtue of Comsat's privileged position in Intelsat and Inmarsat, it would be privy to the workings or direction of thinking of those organizations at an earlier time than other, competing U.S. commercial entities. In recent regulations of the FCC amending rules and policies to conform with the Inmarsat system, the following issue is stated (but not discussed as the rule purportedly covers this point): "[S]ignatories of other countries in the Inmarsat Organization provide to their manufacturers important Inmarsat documents concerning ship earth station specifications which are not made available by the U.S. Signatory, Comsat, to its manufacturers. As a result, manufacturers in other countries have the opportunity to examine these documents in draft form and have an early knowledge of Inmarsat thinking. This gives them a competitive advantage in their business activities with the U.S. manufacturers." [55]

LAWS OF GENERAL APPLICABILITY

In addition to any specific regulatory restrictions, laws of a more general nature may apply to the entry into and/or conduct of operations of space commercial ventures. For example, anticompetitive behavior by and between commercial entities would be subject to the Federal (and State) antitrust laws. One of these laws, the Sherman Act, [56] prohibits contracts, combinations or conspiracies that unreasonably restrain trade, and might well be relevant in such action as the formation of any joint ventures or teaming arrangements. [57] On the other hand, some laws of a general nature may be considered favorable to such potential operations, for example, some of the tax laws are considered for such activities as research and development expenditures and venture capital investments in new technology-based firms. [58]

Private Industry Perceptions

In the light of the previously discussed international situation and domestic regulatory framework, it would seem that private industry might make certain arguments to help establish a posture that too many obstacles or unknowns exist to encourage the commercial risk and expense in most instances by private undertaking.

---

[54] 47 U.S.C. §701 (d)

[55] 48 Fed. Reg. 8460, 8462, March 1, 1983.

[56] 15 U.S.C. §1 et seq.

[57] See, Donald L. Flexner, *The Impact of Antitrust on Commercial Ventures to Exploit Space Technology*, in ALI-ABA Conference Materials, *International Conference on Doing Business in Space: Legal Issues and Practical Problems* (1981), at 305.

[58] See, Report of the National Academy of Public Administration, *Encouraging Business Ventures in Space Technologies* (May 1983), at 35–36.

1. Not only are a number of international law issues concerning space and space activities controversial and unsettled, private rights would be subject to negotiation or even extinguishment under current or future international negotiation pressures.

2. Present U.S. statutory provisions emphasize public (NASA) participation in most space activities or rights thereto, and leave little encouragement or incentive for viable private action.

3. An administrative morass exists concerning private launchings of rockets making it extremely difficult and burdensome to effectuate the necessary clearances in a timely and practical fashion.

4. The establishment by the Congress of a quasi-private entity with certain inherent competitive advantages, including initial access to certain participation and information, presents certain possible commercial impediments to others.

What does private industry want? As a legal optimum, private industry possibly might contend that there should be an express national space policy which includes specific roles, goals or objectives for private commercial ventures, with the minimum amount of Government regulation. Other desires might include Government financial incentives, including such items as direct subsidies, loan guarantees, tax breaks, and limits on liability. If there is to be some Federal agency oversight, it should preferably be by only one. If multiple agencies need be involved, there at least should be one lead agency for industry to deal with and which would be responsive to it. Exemptions from certain general regulatory laws, such as the antitrust laws, should be provided. Proprietary commercial rights should be retained for and by private actions and inventions. Government insurance should be available in the event that private insurers fail or refuse to provide adequate coverage for the risks involved. The Government should provide protection by way of a grandfather clause if future international agreements are negotiated affecting existing private U.S. rights. [59]

Some Recent Legislative Proposals

While a series of earlier proposals in Congress seemed primarily involved with providing investment capital and establishing the necessary business conditions to attract industries to use the space environment to manufacture products and provide services through the creation of a Space Industrialization Corporation to serve as an investment bank, [60] so far in the 98th Congress [as of May 3, 1983] proposals generally seem to involve three tacts, sometimes treated separately or in tandem. The legislation introduced so far that seems to be the broadest in scope is H.R. 1011 (98th Cong.), the "Space Commerce Act." Its stated findings and purpose are:

FINDINGS AND PURPOSE

SEC. 2. (a) FINDINGS.—The Congress finds and declares that—

---

[59] Precedents in a number of these areas with regard to other areas of technology are pointed out in Office of Technology Assessment, *Civilian Space Policy and Applications*, OTA-STI-177, June 1982, at 268-270.

[60] E.g., H.R. 564, 97th Cong.; H.R. 2337, 96th Cong.; and H.R. 14297, 95th Cong. Also, see, Fuqua, *Space Industrialization: Some Legal and Policy Considerations for Private Enterprise*, 8J. Space L. 1 (1980)

(1) the peaceful use of outer space continue to be of great value and to offer benefits to all mankind;

(2) civilian applications of space technology have achieved a significant level of commercial and economic activity, and offer the potential for growth in the future, particularly in the United States;

(3) new and innovative equipment and services are being sought, created, and offered by entreprenuers in telecommunications, information services, and remote sensing technology;

(4) the private sector in the United States has the capability of developing and providing private satellite launching and associated services that would supplement the launching and associated services now available from the United States Government;

(5) cost savings could accrue from the private sector developing and providing launching services;

(6) the development of such services would enable the United States to better compete with the launching services now being developed by foreign countries, thereby contributing to the national interest and economic well- being of the United States;

(7) commercial provision of such services is not inconsistent with the national security interests of the United States;

(8) the United States should encourage and, to the extent reasonable necessary, regulate private sector launching and associated services to provide for the national security and public safety and to carry out the obligations of the United States under international treaties affecting the use of space;

(b) PURPOSE.—It is the purpose of this Act to—

(1) encourage the development of the United States private sector of capabilities for providing launching and associated services;

(2) provide the necessary regulation by the Federal Government to ensure public safety and national security and to carry out obligations of the United States, such as liability for damage from space objects, under applicable international treaties and agreements affecting the use of space;

(3) stimulate private sector applications of Government-developed space technology; and

(4) promote further economic growth and entreprenuerial activity in utilizing the space environment for peaceful activities.

A detailed licensing procedure for a private launching is set forth, and the Secretary of Commerce would be responsible for carrying out the act and providing a designated point of contact within that Department for the licensing procedure as well as to coordinate and facilitate all Federal actions pertinent to private sector launches. The obtaining of liability insurance is a prerequisite for such launchings. The act also would establish a Commercial Space Study Commission to "conduct a study of the direction of future Government involvement in, support of, and regulation of private sector commercial activity in outer space." A similarly motivated bill has been introduced in the Senate, S. 560, the "Private Satellite Launching Authorization Act of 1983," with similar findings, purpose, and policy. It, however, would make the Administrator of the FAA in charge of a licensing procedure (not set forth in the proposal), and also to promulgate regulations concerning safety standards for the design and construction of space launch vehicles and for their launching, as well as liability insurance requirements. A separate bill, S. 955, the "National Commission on Space Act" would establish a National Commission on Space (and covers this aspect in greater detail than H.R. 1011), whose functions, in part, would include:

FUNCTIONS OF THE COMMISSION

SEC. 6. (a) The Commission shall make a comprehensive investigation of exisiting and proposed space activities in the United States in order to assess their adequacy in meeting the present and future needs of the Nation. Such study shall include—

(1) a review of the known and possible economic, social, environmental, foreign policy, and national security needs of the United States, and methods by which space science, technology, and applications initiatives might address those needs;

(2) a review of the adequacy of the Nation's public and private capability in space science, technology, and applications;

(3) a review and assessment of present issues and issues that may arise as space research, technology development, and applications are utilized to meet future national needs; and

(4) an analysis of the findings of the reviews specified in paragraphs (1) through (3) of this subsection, and options and recommendations for a national space policy and program plan.

(b) Issues to be considered pursuant to subsection (a)(3) of this section shall include—

(1) the adequacy of the National Aeronautics and Space Act of 1958 (42 U.S.C. 2451 et seq.) to serve as the basis for future national space policy;

(2) alternative roles and relationships of the civilian and national security space programs;

(3) alternative roles and relationships of the private and public sectors in national space efforts.

(4) the suitability of existing Federal organizational arrangements to carry out future governmental responsibilities in space research, technology development, and applications;

(5) the opportunities for, and barriers to, private sector utilization of the space environment and participation in national space programs;

(6) the methods, occasions, and circumstances under which the Nation should pursue a permanent presence in space; and

(7) considerations involving international cooperation and competition in the utilization of the space environment.

(c) Options and recommendations submitted in accordance with subsection (a)(4) of this section shall include an estimate of costs and time schedules, institutional requirements, and statutory modifications necessary for implementation of such options and recommendations.

Another tact can be found in H.R. 478 (98th Cong.), the "National Space Policy of 1983" (with 64 cosponsors), which is designed to establish the national space policy of the United States. Two of the stated findings are:

(10) the successful development and use of the space environment for scientific and applied purposes depends on continued research and development efforts conducted by the government and private sector; and

(11) the productive development and use of the space environment requires new policies, procedures, and institutional arrangements that encourage initiative by, and use the innovative capabilities of, the private sector.

Two of the declared statements of policy are:

(9) the benefits of space program research to terrestial applications will be maximized by rapid dissemination of information concerning such programs to appropriate public and private bodies; and

(10) the development of space capabilities and systems by the private sector to produce economic benefits to, and to enhance the technological position of, the United States, will be encouraged.

In addition, a number of bills have been introduced which provide, in effect, that the ownership or management of any civil land remote system or meteorological satellite system, or their associated ground systems, cannot be transferred to the private sector

without the approval of the Congress.[61] On April 26, 1983, the House of Representatives passed the NASA authorization bill, H.R. 2065 (98th Cong), to which just such a provision had been added.

Some Possible Future Legal Problems

Private sector involvement in space activities will probably prompt numerous legal problems, particularly as the space technology advances and more human activity takes place in outer space.

CLAIMS

A number of areas may be involved with potential damage to property or injury to persons.

Safety

A regulatory safety regime may be necessary, covering vehicle safety and space worthiness, competency of crews, and design of systems to insure maximum safety of flights and return.[62] The possibility of health emergencies may arise, including Earth quarantines.[63]

Liability

Potential high-technology catastrophic accidents could pose problems. Except for nuclear accidents, NASA's coverage for users of the Space Shuttle and some relatively minor statutes, there is no comprehensive statute dealing with manmade accidents.[64] Responsibilities, obligations, funding, contributions, and claim procedures are the kinds of matters that may need clarification. Other potential claims for liability might arise, such as products liability,[65] which may require resolution mechanisms.

Insurance

Space activity involves new risks, without customary, Earth-oriented perils.[66] Present law covering and permitting NASA to allocate third-party liability risks among the users of the Space Shuttle[67] may not be a viable precedent in other areas, and creative insurance and re-insurance schemes may be called for.[68] At some point, Government participation and/or oversight may be necessary.

JURISDICTION

A great number of problems that are jurisdictional in nature may arise as more diverse commercial activities increase in space and larger numbers of persons spend greater time in that environment. As ownership, financing and participation becomes more multinational, that is, employing more and more citizens or business entities from different nations, as well as proprietary or registered bases in more than one nation or involving international organizations, it may become more difficult to ascertain what laws apply to diverse actions and even who is to make that kind of determination. For example, as satellite ownership becomes increasingly fragmented, "it becomes correspondingly difficult to associate particular treaty and statutory obligations (for example, coordination, tariffs, permissible business practices) with specific entities." [69] Not only may a conflict of law issue arise in any given instance, but questions as to the extraterritorial application of U.S. laws and even the U.S. Constitution may become issues. Certain assertions may even be made under international law. "If all persons in outer space—not merely astronauts and cosmonauts—are assimilated to the status of envoys of mankind and are the subject of international law, some inevitable collisions are perceived between the control of persons in space by the state of nationality and the individual assertion by such persons of internationally recognized human rights and fundamental freedoms." [70]

All sorts of possibilities may exist if analogies are made. Will there be the same sort of "genuine link," salvage, and search and seizure problems that now exist in maritime situations on the high seas? Will specific criminal offense treaties be necessary as has been prompted by crimes committed aboard aircraft?

CONCLUSION

Any ambitious scheme to promote private sector involvement in commercial activities in outer space presents a number of legal problems on several levels. The present regulatory scheme, both international and domestic, for the most part is operationally designed for national interest and responsibility. Any shift of such emphasis to a cross section of private control raises a potential realignment of rights and obligations between the United States and the international community, between the United States and such private sector entities, and between those entities themselves. Legal considerations are crucial on each strata. Adding to the legal complexity is the nature of the activity itself as well as the rapidly evolving technology involved. Great expenditures may be necessary, and high and unforeseen risks may enter the picture. Operational areas are not limited to the territorial confines of the United States, and the potential for calamitous consequences exists.

To facilitate action, among other things it may be necessary to: pinpoint the kinds and extent of commercial involvement that may

[70] Glazer, *Domicile and Industry in Outer Space*, 17 Colum. J. Transnat'l L. 17 (1976).

be practically and politically possible; describe with great detail the form and content of any Government regulation, including a systematic approach as to who, what, when and where private action may be taken; and undertake a close examination as what new international controls may be prudent. Once significant private involvement is forthcoming, any developing legal framework will likely be ongoing. Novel legal problems will probably arise, calling perhaps for new and creative legal theories and enforcement mechanisms.

APPENDIX—SUMMARY OF SPACE COMMERCIALIZATION PROPOSALS

The number of commercial space proposals in areas ranging from expendable launch vehicles to space stations grows almost weekly. The following is a summary of those proposals which could be identified through April 30, 1983. Some are only in the conceptual stage, others are already operational.

In brief, the companies making proposals, according to commercial area, are as follows:

Expendable launch vehicles
- ARC Technologies (Dolphin)
- General Dynamics (Atlas-Centaur)
- Satellite Propulsion, Inc. (Liberty)
- SpaceTran/Martin Marietta (Titan 34D)
- Space Services, Inc. (Delta, Conestoga)
- Transpace Carriers Inc. (Delta)

Reusable space vehicles
- Pacific American Launch Systems (Phoenix)
- Transpace Inc. (Space Van)

Upper stages
- McDonnell Douglas (Payload Assist Module—PAM)
- Orbital Systems Corp. (Transfer Orbit Stage—TOS)

In-Orbit facilities/equipment
- Architects Equities, Inc. (Shuttle payload bay materials processing)
- Ball Aerospace (Shuttle payload bay materials processing)
- Fairchild (Leasecraft, free-flying module for power, telemetry, control, etc.)
- GTI (materials processing furnace—Agreement with NASA terminated)
- Space Industries (space station)

Materials processing experiments
- Battelle Columbus Laboratories
- Beckman Instruments
- Dupont
- EG&G
- Eli Lilly
- Honeywell
- Inco
- John Deere
- Johnson and Johnson/McDonnell Douglas
- Johnson Matthey
- Microgravity Research Associates
- Northrop
- Parker-Hannifan Corp.
- Robert Shaw Associates

A. E. Staley Manufacturing
Terra Mar
TRW
Union Carbide

Space Shuttle
Astrotech International (payload processing facilities at Kennedy Space Center)
Hughes Aircraft (satellite manufacturing and possible payload processing at KSC)
SpaceTran (purchase of a fifth orbiter)

Remote sensing satellite systems

Several companies have indicated interest in operating the existing Landsat system (space and/or ground segments) and possibly the NOAA weather satellites, but no formal proposals have been made at this time. In addition, one company, American Science and Technology, has proposed developing and launching its own remote sensing satellites although its proposal is not formal yet, either.

Existing NASA Mechanisms for Encouraging Commercial Space Activities

There are currently three types of agreements which NASA uses in facilitating Government/industry cooperation in commercial space endeavors: A cooperative agreement, a joint endeavor agreement, and a technical exchange agreement. [1] The differences between the three are slight, and which one is used for a particular activity depends primarily upon which NASA office is in charge of the agreement. For example, the joint endeavor and technical exchange agreements are used primarily for materials processing experiments—the former most often when an actual flight experiment is contemplated, the latter when experimentation primarily takes place on the ground. The term "cooperative agreement" was initially coined as part of NASA's international activities and denoted an agreement between NASA and another country in which no exchange of funds occurred. Its meaning has now been extended to commercialization activities between NASA and the private sector, such as the agreement with Orbital Systems Corp. for development of an upper stage.

Expendable Launch Vehicles/Upper Stages

There are currently four expendable launch vehicles (ELV's) in use in the United States: Titan, used primarily by the DOD and manufactured by Martin Marietta; Delta, used primarily by NASA and manufactured by McDonnell Douglas; Atlas, used by both NASA and DOD and manufactured by General Dynamics; and Scout, used primarily by NASA for very small payloads, and manufactured by LTV Aerospace. Proposals to commercialize the first three of these systems have already been made public. Martin Marietta, in conjunction with SpaceTran Inc., is actively marketing its Titan 34D vehicle, while General Dynamics is similarly marketing

[1] Information for this section is based on a meeting and subsequent telephone conversations with a NASA representative, April 1983.

its Atlas-Centaur. McDonnell Douglas has no plans at this time to market the Delta, although two other companies, Transpace Carriers Inc. and Space Services. Inc. have shown interest in this ELV. Both companies are holding discussions with McDonnell Douglas concerning their proposals, but no definitive arrangements have been made.

Three companies are in the process of developing their own ELV's: Space Services, Inc. is developing the Conestoga rocket based on Minuteman technology and has successfully completed one suborbital test flight; ARC Technologies of Redwood City, Calif. is developing the Dolphin which will be launched from the ocean rather than land, and is initially being developed as a suborbital sounding rocket; and Satellite Propulsion, Inc. of Beverly Hills, Calif. is considering development of an ELV called Liberty to compete with Atlas-Centaur.

There are also several upper stages used with the ELV's and/or with the Shuttle: the Payload Assist Module (PAM), developed and manufactured by McDonnell Douglas; the Inertial Upper Stage (IUS), developed under Government contract and manufactured by Boeing; Centaur, developed under Government contract and manufactured by General Dynamics with a new version for use with the Shuttle now in development; and the Transfer Orbit Stage (TOS) being developed privately by Orbital Systems Corp. under a cooperative agreement with NASA.

The following tables summarize the characteristics of the ELV's and upper stages that are being proposed for commercialization.

U.S. Expendable Launch Vehicles Proposed for Commercial Operations

Vehicle [1]	Manufacturer	Entity planning to commercialize	Fuel type	Payload weight to orbit, [2] comments
Dolphin	ARC Technologies	ARC Technologies	Hybrid	Suborbital. 500–2,000 lbs to 100–300 miles altitude. Vehicle being privately developed; may have orbital version later.
Liberty	Satellite Propulsion Inc.	Satellite Propulsion Inc.	Liquid	6,300 lbs to LEO (due east) 4,500 lbs to GTO. Vehicle being privately developed.
Atlas-Centaur	General Dynamics	General Dynamics	Cryogenic	5,200 lbs to GTO in 1983; improvements to 14,000 lbs to GTO planned. Developed under Government contract.
Conestoga	Space Services, Inc.	Space Services, Inc.	Solid	500 lbs to LEO (polar orbit). Vehicle being privately developed.
Delta 3910/3970 (with PAM)	McDonnell Douglas	TranSpace Carriers; Space Services, Inc.	Liquid	5,500 lbs to LEO. Delta 3910 can put 2,450 lbs in GTO. Delta 3920 can put 2,800 lbs in GTO. Vehicle developed under Government contract.

U.S. Expendable Launch Vehicles Proposed for Commercial Operations–Continued

Vehicle [1]	Manufacturer	Entity planning to commercialize	Fuel type	Payload weight to orbit, [2] comments
Titan 34D	Martin Marietta	SpaceTran/Martin Marietta	Liquid	31,000 lbs to LEO. Can put 5,600–6,000 lbs in GEO assuming satellite has own kick stage. Vehicle developed under Government contract.

[1] Launch vehicles typically have several different versions each with different capabilities. The version(s) listed here are those specifically for which commercialization proposals have been made.

[2] LEO is low Earth orbit. GEO is geostationary Earth orbit. GTO is geostationary transfer orbit, an eccentric orbit into which a payload is initially placed, after which an additional kick stage is used to circularize the orbit at GEO. Approximately half the payload weight to GTO is taken to GEO. All payload weights are in pounds (lbs).

Source: All data were obtained from the companies involved in manufacturing or commercializing the vehicle, or NASA.

U.S. Upper Stages

Vehicle	Manufacturer	Used in conjunction with	Fuel type	Payload to GEO	Comments
Centaur	General Dynamics	Shuttle [2]	Cryogenic	10,600 lbs. [2]	In development under Government contract. [2]
IUS	Boeing	Shuttle or Titan	Solid	5,000 lbs	In use, but failed its second launch in March 1983. Developed under Government contract.
PAM D	McDonnell Douglas	Shuttle or Delta	Solid	2,750 lbs. [1]	In Use.
PAM D II	McDonnell Douglas	Shuttle or Delta	Solid	3,500–3,900 lbs. [1]	In Development.
PAM A	McDonnell Douglas	Shuttle or Delta	Solid	4,400 lbs. [1]	Developed privately by McDonnell Douglas.
TOS	Orbital Systems Corp.	Shuttle	Solid	2,800–6,800 lbs.	In development. Being developed privatly by OSC.

[1] Indicates payload weight is to geostationary transfer orbit, not geostationary orbit (GEO).

[2] Centaur can also be used with Atlas and Titan, but the version here is the one in development for use with the Shuttle. The company also plans to develop a version with a 14,000 lb capability for planetary missions. Centaur can have a greater payload capability with improvements in Shuttle system.

Source: All data were obtained from the manufacturers or NASA.

Reusable Space Launch Systems

Two concepts for reusable space launch systems which could be used in either a manned or unmanned mode are also being promoted. Both are still in the conceptual stage, and the sponsors have not yet found financing.

The first is called Space Van and is being offered by a company called Transpace Inc. (not to be confused with Transpace Carriers Inc. which is proposing to commercialize the Delta), headed by Len Cormier of Washington, D.C. [2] Space Van could be used in an unmanned "cargo" mode or a manned "orbiter" mode. In the former

[2] The Amazing Private Mini-Shuttle. Space Digest, August 1982, pp. 80–81. Proposed Space Van Wants to Challenge Shuttle for Small Payloads. Satellite Week, October 19, 1981, p. 5. Information also obtained directly from Transpace Inc.

type of mission, the vehicle would operate as a reusable booster with an expendable space stage. In the latter, it would be similar to the Space Shuttle. In both cases, it would be launched from a 747 aircraft, and use Pratt & Whitney RL-10 cryogenic engines. In the cargo mode, a payload of 6,600 pounds could be placed into a 280 mile orbit. Payloads of 1,760 pounds could be placed in geosynchronous orbit, unless low-orbit refueling was used, in which case 6,600 pounds could be placed there. According to its promoters, it might reduce costs to one-fifth that of the Shuttle.

The second concept is for a reusable manned or unmanned launch vehicle called Phoenix. Promoted by Pacific American Launch Systems, Inc., Phoenix would be very versatile according to its creator, Gary Hudson of Redwood City, Calif., and could be used for missions to low Earth orbit, geosynchronous orbit, or even to the Moon. [3] Phoenix would be a single stage vehicle using high efficiency, liquid fueled engines (liquid oxygen, hydrogen, and propane) and would be able to place 5,000-10,000 pounds into GEO without requiring an upper stage. According to Hudson, the Phoenix will be considerably less expensive than the Space Shuttle to launch ($50 million for use of an entire Phoenix vehicle in 1986, compared to an expected $70 million for an entire Space Shuttle flight—actual prices for use of either will depend on the size and weight of the payload).

In-Orbit Space Facilities

Several companies have set forth plans for developing space facilities as cooperative efforts with NASA.

Fairchild Industries of Germantown, Md. signed a memorandum of understanding (MOU) with NASA in September 1982 initiating discussion for the proposed development of a mini space platform called Leasecraft. [4] The facility could be left in space for indefinite periods of time (the Shuttle is currently designed for orbital stay times of two weeks or less), and be tended by the Shuttle on subsequent missions. Leasecraft would provide power, stabilization, communications, and orbital adjustment capabilities for various payloads, and would be based on the Multimission Modular Spacecraft designed for NASA by Fairchild and used already for the Solar Maximum Mission and Landsat 4. Under the MOU, NASA and Fairchild will study Leasecraft with the goal of having it available in orbit by 1986. Fairchild would be responsible for leasing space to government and industry users. Among the payloads expected to require such a facility are materials processing and biological processing plants, and astronomical observatories. NASA would launch Leasecraft for Fairchild in exchange for free use of the platform for certain periods.

A second proposal is by a Houston based company, Space Industries. One of the founders of the company is retired NASA spacecraft designer Maxime Faget who was instrumental in designing

[4] Potential of Mini Space Platform to be Studied. NASA Press Release 82-141, September 28, 1982.

both Apollo and Space Shuttle. Space Industries signed an MOU with NASA in late 1982 to study the private development of portions of a space station.

Architects Equities Inc. (Champaign, Ill.), has proposed a computer-aided space factory to be operated in the Shuttle by remote control from the ground or with preprogramed robots. The proposal was in response to NASA's request for proposals on space station studies, but did not meet the criteria for actually submitting a bid since it did not meet all mission requirements and the company is not adequately staffed. NASA is reportedly interested in the idea, however. [5]

Ball Aerospace Systems is considering the construction of a facility in which to carry payloads in the Shuttle cargo bay, and signed a memorandum of understanding with NASA in September 1982 to work on development of a joint endeavor agreement. [6]

In 1982, NASA signed a joint endeavor agreement with GTI Corp. for development of a furnace for metallurgical research which would have been mounted in the Shuttle payload bay. After 1 year and an expenditure of approximately $600,000 of its own money, GTI terminated the joint endeavor agreement in the spring of 1983 because it saw no market for the device at this time, and because NASA had not developed the carrier device needed to mount the furnace in the payload bay (construction of the furnace could not proceed without knowledge of that interface). [7]

Materials Processing in Space

Among the areas in which NASA expects substantial commercial activity in the next several years is materials processing in space (MPS). This field includes processes which benefit from the lack of gravity in space, such as electrophoresis (in which biological products are separated from their solution by passing an electric current through the fluid), the growth of more perfect crystals (for use in electronic chips, for example), and the creation of new metal alloys.

NASA experimented with MPS during the Apollo and Skylab programs, although the total amount of time spent on such activities during those programs was only about 8 hours. NASA's joint endeavor program is one method for assisting private industry to perform MPS experiments. Only three joint endeavor agreements have been signed for MPS, however, and one of these has subsequently been terminated. The first, with McDonnell Douglas and Ortho Pharmaceuticals (a division of Johnson and Johnson), concerns electrophoresis, and an experimental device has been flown on two of the six Shuttle missions to date. Three more flights are planned in the series, after which McDonnell Douglas/Ortho may proceed to space factory production. The second joint endeavor was the one with GTI for an MPS furnace discussed previously, while the third is with Microgravity Research Associates, signed in April

1983, for development of a process for making semiconductor materials.

In addition to the joint endeavor agreements, NASA has also signed a technical exchange agreement with John Deere and Co. to study the effects of microgravity on iron alloys. The agreement, signed between NASA's Marshall Space Flight Center and Deere in July 1981, provides for Deere to use NASA's low-gravity facilities (such as drop tubes and sounding rockets) to conduct research which might lead to future experiments aboard the Space Shuttle. Data is exchanged between the two parties in return for Deere's access to the NASA facilities. Technical exchange agreements have also been signed with Honeywell, Inco, and Dupont,

Other companies reportedly pursuing work related to MPS include: Battelle Columbus Labs, Union Carbide, TRW, A.E. Staley Manufacturing, Beckman Instruments, EG&G, Robert Shaw Associates, Northrop, Terra Mar, Parker-Hannifin Corp., Eli Lilly, and Johnson Matthey, Inc. [8]

Space Shuttle

Several proposals have been made in connection with commercial opportunities associated with the Shuttle. Two of these involve private companies building payload processing facilities near Kennedy Space Center (KSC). NASA is currently in charge of payload processing, but its facilities are overworked. In 1983, Astrotech International announced plans to build a payload processing facility near KSC, and through an exchange of letters made arrangements with NASA to ensure that payloads processed there would meet NASA standards. Hughes Aircraft is also actively considering a payload processing facility near KSC in conjunction with a satellite assembly plant there.

A different type of Shuttle-related proposal was received by NASA in 1982 from SpaceTran Inc., a Princeton, N.J. based firm. SpaceTran offered to purchase a fifth Shuttle orbiter for NASA in exchange for exclusive marketing rights to commercial and foreign users of the Shuttle system. The proposal is undergoing negotiation at the present time and details of changes that have been requested by NASA have not been made public. SpaceTran, which is partially owned by Prudential Insurance Co., is currently in a transition phase following the purchase of 20 percent of the company by Federal Express in early 1983.

Remote Sensing

As noted earlier, no formal proposals have been made for commercializing the civil land and weather remote sensing satellite programs, although the Reagan administration announced plans for such a transfer of operations to the private sector in March 1983.

---

[8] These companies have been identified in the following manner: Battelle—telephone conversation with company representative, April 1983; Union Carbide—Aerospace Daily, January 6, 1983, p. 30; TRW, Staley, Beckman, EG&G, Robert Shaw Assoc., Northup, Terra Mar, and Parker-Hannifan—identified by Robert Sharples of TRW as participants in a TRW-sponsored workshop in October 1982 for companies pursuing MPS work in a telephone conversation, April 1983; Eli Lilly and John Matthey—Aerospace Daily, April 22, 1983, p. 309.

In 1982, NOAA, which currently operates these systems, issued a request for information to companies interested in potential operation of the systems and several companies responded. Only one, Comsat, presented a plan for operating both the space and ground segments of the land and weather satellite systems. Comsat's response included possible terms that it might make in a formal proposal to the Government, which included purchase of the existing system for $250–$350 million, plus a guaranteed Government data purchase of approximately $300 million per year for 15 years. Other companies (including Hughes, RCA, General Electric, Control Data Corp.) indicated interest in parts of the Landsat ground segment, but not the satellites themselves.

One company, American Science and Technology (AS&T), has proposed constructing its own remote sensing satellites for launch using the Conestoga launch vehicle. Space Services, Inc., developers of the Conestoga, is a majority stockholder in AS&T.

THE NEXT 25 YEARS: INDUSTRIALIZATION OF SPACE

- RATIONALE FOR PLANNING -

Jesco von Puttkamer*
Advanced Programs

Washington, D.C.

1. Humanizing Space

Dreams about mankind emigrating into space are as old as science fiction. Concepts of permanently occupied and self-sufficient extraterrestrial outposts, bases, habitats, and colonies for settling space have long been envisioned in Earth orbits, on the Moon and on other celestial bodies such as Mars or larger asteroids. More recently, serious writers have suggested that such goals are possible in reality within the foreseeable future, e.g., O'Neill in 1974 (Reference 1). Results from recent NASA studies are generally in support of this work (Reference 2). Some of these projections have included the suggestion that space colonies would be the answer to the "population explosion" on Earth.

Should our next major goal in space, then, be to

establish a colony in space for - say - 10,000 people as proposed by recent studies?

The industrially advanced nations are no longer threatened by overpopulation as are many developing nations. Thus, by not answering a demographic or social need for that part of the world that would have to underwrite the effort, space colonization per se is unable to contribute to a lessening of population pressures in the relevant future.

While space colonization as initial objective and dominant program thrust is clearly not the answer, mankind's expansion into space will be unavoidable in the long run for sheer survival. There can be little doubt that permanent settlements in space will be in mankind's future, and it is one of our most important obligations to future generations to keep these and other growth options open at this time where we are but at the threshold of new frontiers. As the uncertainty about these new frontiers and the possibility of future crisis conditions rise, "safety" lies in maximizing the option potential open to future mankind, to avoid foreseeable and reduce unforeseeable problems.

At the same time, planning of the next steps must be responsive to mankind's near-term needs and wants, while

building a solid foundation of ethical responsibility and technological capability from which an open, choiceful long-term future (or futures) becomes accessible. That alone will provide validity to the Space Program.

In planning the long-range space program based on essentially utilitarian aspects of the near-term without losing sight of the more humanistically significant long-term, and to forecast associated technology requirements, a planning methodology was developed which has recourse to a combination of two basic modes of planning (FIG. 1), extrapolative and normative (Reference 3). In the extrapolative view, responding to the "Push", alternative futures are projected on the basis of past and current trends and tendencies. In the normative view, establishing a "Pull", some ideal state in the far future is envisioned or postulated, and policies and decisions are directed toward its attainment. While the extrapolative view is strictly rational, "cold", and without value statement, the normative planning is truly idealistic, by basing its futures on human values and aspirations, and it would therefore require a value consensus ("Whose norm?"). By not limiting the norms under investigation and keeping all those future options open that appear to be supported

INTEGRATED LONG-RANGE PROGRAM PLANNING

TWO BASIC MODES

EXTRAPOLATIVE VIEW ("PUSH")

- PROJECTS ALTERNATIVE FUTURES ON BASIS OF PAST AND PRESENT TRENDS
- BASES POLICY GUIDANCE ACCORDINGLY
- MAY MISJUDGE CURRENT TREND(S)
- OFTEN FAILS TO SEE THAT SHORT TERM ACTIONS LEAD TO LONG TERM CONSEQUENCES THAT MAY BE UNANTICIPATED AND UNDESIRABLE
- IS ESSENTIALLY VALUELESS, BUT CAN MODIFY TREND LINE IF FUTURE CONTEXT CHANGES

NORMATIVE VIEW ("PULL")

- ENVISIONS IDEAL STATE IN FAR FUTURE AND DIRECTS POLICY & DECISION TOWARD ITS ATTAINMENT
- DEVELOPS FUTURE(S) BASED ON HUMAN VALUES AND ASPIRATIONS
- "FEEDS" FUTURE IMAGE BACK TO PRESENT PERCEPTION OF REALITY AND FACILITATES VALUE CONSCIOUS PLANNING (TIME REVERSAL OF CAUSALITY)
- REQUIRES VALUE CONSENSUS ("Whose norm is to be used?")

REALISTIC APPROACH

- COMBINATION OF BOTH MODES
- PROJECT FORWARD FROM PRESENT WITH EXTRAPOLATION ADJUSTED OVER TIME
- FEED BACK FROM IDEAL FUTURE, RELYING ON EXTRAPOLATIVE GROUNDINGS
- IN PRACTICE: DEVELOP "STEPPING STONES" (INCREMENTS) TO THE FUTURE WHICH ALLOW
  - ASSESSMENT OF BOTH THEIR "BEFORE" AND "AFTER" IN NORMAL AND TIME-REVERSED CAUSALITY.
  - AD HOC ADJUSTMENT OF TREND LINE IN RESPONSE TO NORMATIVE CONTEXT AND EVOLUTIONARY TRENDS.

ORIGINAL PAGE IS OF POOR QUALITY

FIG. 1

by some consensus at present, the problem of deciding whose norm should be baselined can be avoided. A combination of both modes can then yield a more realistic approach to integrated long-range planning by tieing time-reversed vectors of the future to extrapolated, trend-oriented vectors of the quasi-present in a "tree of relevance". By defining development plateaus, common stepping stones can be identified. The "Push/Pull" planning approach, for the first time, appears to offer a useful relationship between utilitarian and humanistic goals of space flight (FIG. 2.)

In thus aiming at long-range goals of humanizing space through colonization, Space Industrialization must first generate an open world that would - through its "re-started" growth processes - make space colonization tenable, supportable and practical. Once established in space, permanent settlements will tap the energy and resources of space, thus easing the mounting human pressure on Earth's dwindling resources, helping remove much industrial activity from the fragile biosphere of Earth, and providing new "frontier" challenge and new worlds for humankind.

2. Opening the Closed World

In our present world, both the industrialized and industrializing countries are facing monumental problems. But even more alarming is the dilemma of the nonindustrialized, undereducated, undernourished and undercapitalized nations. Rapidly approaching or already faced with excess population levels, they must undergo social changes at a considerably higher rate than all other countries in history. Their combined growth, based on current rate, will result in well over a billion new people in the next 20-25 years. Extrapolations of this type have led concerned people to seriously consider the Unspeakable, - namely, the imposing of "limits to growth".

There are no longer empty continents with lush vegetations into which excess populations could migrate. Space colonization, as stated before, is not (yet) an answer. Population control is an important nearer-term response, but the inertia-like time lag between birth-rate decline and slowdown in population growth and population stabilization will be many decades (typically 100 years to level off assuming the net reproduction rate reduced to 1.0 by 2025) during which population will continue to grow vigorously (to 10-12 billion at level-off point). Higher

productivity through industry, generation of more capital in the undercapitalized world, and creation of new values and jobs will have to go hand-in-hand with population control to bring the standard-of-living - and the natural acceptance of lower birth rates - of the "developed", highly industrialized countries to both the developing but raw-material-rich and the developing and raw-material-poor nations, in terms of gross national product (GNP), per capita income, energy, food and material consumption, and population index (Reference 4).

3. Goals of Space Industrialization

The intensification and expansion of Earth-based industrialization to support such a global-wide standard-of-living increase at the population levels predicted for the next 30-40 years (requiring an increase of industrialization above current levels by an estimated factor of 35-40) has given cause for serious concern of energy and raw materials availability as well as environmental burden due to waste products, waste heat, and pollutants, supporting the simple fact that in a limited world - as in a shrinking droplet of water - growth is limited. For humans living in such a no-growth world, there will be only one choice: to organize scarcity. As a result, their

future will quite likely be characterized by scarcities, deficiencies, shortfalls, defensive Earth resources policies, regression to intensified battle for survival, and new fragmentation of mankind. Thus, in a closed world, a fourth complex of problems joins the dilemma of population increase vs. living standard vs. environment: social strife and warfare.

For the opening of the essentially two-dimensional world with its "flat", closed surface limited in resources, energy and human real estate, to the three-dimensional environment of space to be effective, space must contribute to removing the limits to growth by not only generating new products and services but, in fact, by "shunting" energy- and pollution-intensive components of Earth industry into space where both energy and waste reservoir are plentiful (Reference 5). In addition to organizing scarcity to preserve, recycle and substitute for limited resources, a second choice becomes viable: the creation of wealth for all mankind without detrimental environmental impact.

Foremost among the needs faced by the large majority of mankind (over 70%) are industrial development and

diversification, unemployment, population growth rate, agricultural development and food supply, rural and urban development, and health and education. For the industrialized nations, additional concerns pertain to energy shortage and independence, raw materials depletion, environmental burden, and inflation/recession. Clearly, to be morally supportable, Space Industrialization must contribute to the solution of these problems, both on a national (U.S.) level and - eventually - on a global scale.

The goals of NASA's Space Industrialization program, thus, include making a major contribution to increased productivity on Earth without taxing the environment, generating new values through extraterrestrial productivity, and providing new growth options for the future which would include permanent settlement of space and long-range colonization and exploration projects.

The task of balancing the needs of mankind with the requirements of maintaining the Earth's biosphere through the industrialization of space will - by necessity - be approached through a step-by-step evolution.

4. Stepping Stones

Space Industrialization, by developing the permanent and productive use of environments beyond Earth, must be based on the economic principles of cost effectiveness and commercial competition. This in itself presupposes the introduction of "stepping stones" to the overarching concept of Space Industrialization in order to facilitate the transfer of the investment capitalization from the public (Federal Government) sector to private industry. Since capital cost and interest rates are significantly affected, as is inflation, by the length of time and the extent to which investment capital is tied down unproductively in development (requiring discounting), return (pay-back) times on investment and the time until breakeven must be minimized. In addition, the higher the confidence level that influential features of the future Space Industrialization systems/programs can be maintained within acceptable tolerance bands, the lower the risk to the investor. Both arguments stipulate a stepping-stones approach that provides "manageable" increments within the "Push/Pull" force field of the overarching (long-range) concept.

In addition to providing reduced investment steps and shorter pay-back times, the pre-planned plateau approach (Reference 3) or "technique of small steps" allows

- Goal-oriented program planning and management,
- Built-in "holds" for successive re-evaluation of subsequent goals and objectives,
- Built-in "holds" for introduction of new technologies, both improvements and replacements/breakthroughs, and
- Better assimilation of space progress in Earth's culture and concurrent consolidation of technological progress with (slower) humanistic/cultural development.

By expanding the biosphere to include the space dimension, access is obtained to functionally infinite materials and practically infinite energy supplies. Some of the attributes and resources of space that are of relevance are listed in TABLE 1.

Based on this wealth of potentially attractive features, the guiding principles of Space Industrialization must therefore be to (a) exploit the availability of virtually unlimited energy, (b) exploit the excellent transmission characteristics for energy and information, (c) exploit the large geometrical coverage, and (d) exploit the benign environment (except for radiation belts). A summary of candidate activities is given on FIGs. 3a and 3b (Reference 4).

- Easy gravity control from ambient zero-g (or micro-g) to any desired rotationally induced multi-g-level
- Absence of atmosphere -
  - unhampered viewing of space for astronomy, astrophysics, etc.
  - perfect vacuum and freedom from seismic, acoustic, and convection disturbances
- Comprehensive overview of Earth surface and atmosphere
- Isolation from Earth's biosphere (for hazardous processes)
- Freely available light, heat, and power
- Infinite natural reservoir for
  - unlimited disposal of waste products
  - safe storage of radioactive products
- Super-cold temperatures (heat sink)
- Large, three-dimensional volumes (storage, structures)
- Variety of non-diffuse (directed) radiation
- Magnetic field
- Extraterrestrial raw materials

USEFUL ATTRIBUTES OF SPACE

TABLE 1

SPACE INDUSTRIALIZATION
EXAMPLES OF OPPORTUNITIES - 1

INFORMATION TRANSMISSION FOR PUBLIC SERVICES

- COMMUNICATION: Person-to-person, Voting/polling, etc.
- DATA TRANSMISSION: Electronic mail, Package tracking, Surveillance
- NAVIGATION/TRAFFIC CONTROL: Personal, Air Traffic, Ships
- INFORMATION STORAGE: For Recall from Earth or Space, Computer in Space.
- PUBLIC INFORMATION SERVICE: Education, Cultural/entertainment programs.

DATA ACQUISITION/TRANSMISSION

- METEOROLOGY: Accurate Weather Predictions
- PROBING OF ATMOSPHERIC LAYERS: Ozone layer, Ionosphere
- LAND MONITORING: Resources, Fault zones, Earthquake areas, coasts.
- OCEAN MONITORING: Currents, Wave conditions, Icebergs, Marine life
- COLLECTION/TRANSMISSION FROM SURFACE BUOYS AND BALLOONS
- SOLAR ACTIVITY MONITORING: Flare warning, etc.

EARTH-ORIENTED TELEOPERATION AND TELEMONITORING

- LONG PIPELINES AND POWER LINES
- REMOTE INDUSTRIAL FACILITIES: Desert Solar Power Stations, etc.
- REMOTE AGRICULTURAL FACILITIES
- REMOTE HUMAN ACTIVITIES: Expeditions, Search/Rescue, etc.

NUCLEAR WASTE DISPOSAL

- FROM EARTH SURFACE: To long-lifetime orbits or Sun
- FROM VICINITY OF ORBITING INDUSTRIAL FACILITIES

FIG. 3a

NASA HQ M76 4087A (1)
8 24 76

SPACE INDUSTRIALIZATION
EXAMPLES OF OPPORTUNITIES - 2

MANUFACTURING IN LOW EARTH ORBIT

- HIGH-COST LOW-WEIGHT/VOLUME PRODUCTS: from Earth-supplied Materials
- STRUCTURES & STRUCTURAL ELEMENTS FOR SPACE FACILITIES: from Earth- or Moon-supplied Materials

SPACE LIGHT (ILLUMINATION FROM SPACE)

- INDUSTRIAL/AGRICULTURAL OPERATIONS, COMMERCIAL TRAFFIC, URBAN AREAS
- FOOD PRODUCTION: Plankton growth, etc.
- WEATHER MODIFICATION: Crop damage prevention.

SPACE MICROWAVE POWER (ENERGY FROM SPACE)

- LONG-DISTANCE RELAY OF POWER FROM SOURCE TO USER CENTER
- SPACE-GENERATED POWER TO TERRESTRIAL USER CENTER
- SPACE-GENERATED POWER TO SPACE INDUSTRIAL FACILITIES

LUNAR INDUSTRIALIZATION

- SUPPLY OF OXYGEN FOR ROCKET PROPULSION/LIFE SUPPORT: Transportation
- STRUCTURAL & MANUFACTURED GOODS TO ORBITING FACILITIES
- PRIMARY COMMODITIES & MANUFACTURED GOODS TO EARTH

HUMAN ACTIVITIES

- MEDICAL/THERAPEUTIC SERVICES/OPPORTUNITIES: Curative & Alleviative
- RECREATION: Space Tourism Facilities

SOLAR SYSTEM INDUSTRIALIZATION

- MARS: STAGING & SUPPLY BASE FOR ASTEROIDAL UTILIZATION
- ASTEROIDAL METALS FOR EARTH
- HELIOCENTRIC EXPLORATION

FIG. 3b

NASA HQ MT/G 408/III (1)
R 74 /b

As a logical consequence, Space Industrialization introduces several new and interlinked commonality features that will become characteristic of future space activities, viz.,

- Large structures in space
- Complex systems in space
- Long flight durations
- Manned orbital service and maintenance.

While the long-range motivation of Space Industrialization, the "Pull", is physical and humanistic expansion - and thus survival - of mankind, the nearer-term goals of Space Industrialization are three-fold: provide energy from space, provide space-derived products or goods that are salable and profitable, and furnish space-derived services for which agencies, industries and the public are willing to pay.

5. Applications

ENERGY. The problem of satisfying the energy demand of the industrialized world, as currently perceived, will reach near-critical proportions over the next 25 years. The electric power capacity of the U.S. alone is expected

to triple (from 500 GW to 1500 GW) before 2000, requiring investments on the order of a trillion dollars, and to continue to grow. There is no obvious single source to supply this demand growth: Oil, gas and conventional nuclear power generation uses depleting, irreplaceable resources (i.e., living off "capital"); nuclear fusion development is uncertain at this time, and its costs are unknown; solar-terrestrial power (photovoltaic, thermal, wind, etc.) appears to be penalized by high cost and the problem of energy storage.

Without Space Industrialization, prospects for power sources by 2000 appear to be limited to coal, using existing technology, and breeder reactors, requiring development*) For both options, there exist problems of environmental burden and potentially high cost. An additional problem, pointed out by K. Ehricke, is the high cost of electrical power transmission, requiring presently more than 400,000 miles of high-voltage lines in the U.S., with 11,000 square miles of right-of-way real estate.

The potential benefits of Space Industrialization to the energy problem can be three-fold:

*) First breeder reactor is expected to come on line about 1992-93, with doubling time (for fuel) of 30-60 years, improving to 20 years thereafter.

- by providing technology useful for generating and/or transmitting power on the ground,
- by providing RF power reflectors in space for passively relaying electrical power from ground power plants to ground users, and
- by generating power in space for transmission to the ground.

Replacing the current 64 kV transmission lines with higher-voltage cables is one answer to the power transmission problem. Switching from AC to DC power may be a better, more economic solution, according to Rockwell International, but it would require high-voltage AC/DC rectifiers and inverters. Such devices use terrestrially produced silicon crystals of 4-7 cm diameter (where size determines maximum power level). By producing these crystals in space, a choice of sizes up to 15 cm could be provided, allowing a reduction in number of crystals needed for a given power level to 7% of the number of 4 cm crystals. Potential cost savings due to reduced construction requirements are estimated at $76.5 billion by 2000 (assuming 1000 GW generating capacity).

Even more significant may be the impact of "clean" power generated from solar energy from space. For solar-terrestrial (ground) collectors, availability of the Sun is roughly 17% of the time in Arizona and 6% average

nation-wide (Reference 6). By relocating the solar collector array from the day/night cycle and atmospheric environment of the ground to a suitable Earth orbit, solar radiation would be available over 99% of the time, limited only by occasional passes through Earth's shadow. This means that a power collector in space (11,800 kWh/m^2 per year) would intercept almost 6 times as much as one in Arizona (2000 kWh/m^2 annually), and almost 17 times as much as the U.S. ground average (700 kWh/m^2-year).

After collection of the energy in geosynchronous orbit, electricity would be generated in space through one of a number of possible conversion techniques, listed below. For subsequent transmission to Earth (or to a space-based industrial facility complex), the DC electricity would be converted to microwave RF through amplitrons (vacuum-tube type amplifiers such as klystrons are unnecessary in the vacuum of space), and beamed to a receiver antenna (rectenna) on Earth. Atmospheric transmission losses for microwave energy at the 2.45 GHz level would amount to no more than 2-8%. The entire DC-to-DC transmission chain itself is expected to achieve a level of about 58% efficiency (Reference 7).

Conversion techniques, presently under investigation by NASA and its contractors, may be photovoltaic (light energy) or solar-thermal (heat energy). The latter category includes thermionic, Brayton-cycle, thermionic Brayton-cycle, and Rankine-cycle systems. The former uses vast arrays of solar cells (silicon). Overall efficiencies of solar power satellites (from interception to AC ground power busbar) are estimated at 4-8% for photovoltaic, 6-17% for thermal systems.

To make the solar power satellite system economically viable, a considerable amount of power must be delivered, requiring very large collector arrays. For a ground power output of 10 GW, a photovoltaic array would cover an area of 129 km^2 and have a mass of 34,000 metric tons. Its development costs are estimated at $50 billion, its energy production cost at 27 mils/kWh. For comparison, a Brayton-cycle thermal satellite system would require only 70 km^2 of size, but 151,000 tons of mass, $59 billion of development cost, and 50 mils/kWh of energy production cost (Reference 7).

If sold "at cost" of $.027 per kilowatt-hour, the power output of a photovoltaic satellite would yield an annual revenue of $2 billion, i.e., a square kilometer of space would return more than $15,500,000 each year.

PRODUCTS (Goods and Services). Exploitation of the unique environment of space for processing of commercial inorganic and biological/pharmaceutical materials as well as manufacturing of new products designed to enhance productivity on Earth are expected to develop very high industrial potential. Not only would such activities affect world trade and lead to lower costs, thus benefitting national and global economy, but they would also be of importance to human health by benefitting disease prevention and more effective treatment.

At present, we know of five basic types of industrial processes that require a zero-g environment for improved material quality, more efficient material utilization, commercially significant production volume, and lower cost:

1. Crystal growth, including growth from a melt, growth in solution, and growth from the vapor phase.
2. Purification/separation.
3. Mixing.
4. Solidifications.
5. Processes in fluids.

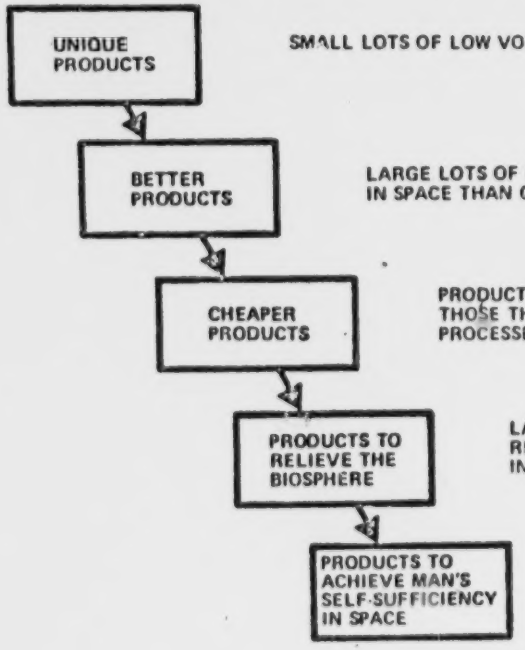
Other processes require high vacuum, such as vapor deposition techniques.

The possible evolution of Space Processing and Manufacturing of Goods along plateaus or stepping stones of immediate and contemporary benefit toward far-future goals of Space Colonization are highlighted in FIG. 4. Again, the stepping-stone approach would allow sponsorship by the Government during the high-risk concept formulation phase, with subsequent shift of emphasis to private/commercial investment. The detailed plans for government/industry interaction have yet to be constructed and are presently under early study; however, they can be expected to vary with the product or service produced.

Top candidates on NASA's list of inorganic commercial products made in space are semiconductor materials such as silicon or gallium-arsenide ribbons for wafers and chips, vapor-deposited solar cells, and niobate crystals for lasers and memories. For example (Reference 8), producing crystal chips in the gravity field on Earth from cylindrical boules yields 37% of useable wafers which in turn are processed into 21% of tiny electronic chips for integrated circuit (IC) substrates, resulting in an overall yield of 8%. For comparison, processing of the semiconductor material in ze. g in ribbon-form would bypass the wafer stage and lead directly to chips, with an overall

EVOLUTION OF SPACE INDUSTRIALIZATION

EXAMPLE: SPACE PROCESSING & MANUFACTURING OF GOODS



SMALL LOTS OF LOW VOLUME/HIGH VALUE GOODS THAT CAN ONLY BE MADE IN SPACE

LARGE LOTS OF HIGH VALUE GOODS THAT CAN BETTER BE MADE IN SPACE THAN ON EARTH

PRODUCTS THAT ARE CHEAPER MADE IN SPACE, SUCH AS THOSE THAT RESULT AS BY PRODUCTS FROM PRIMARY PROCESSES

LARGE VOLUME/LOWER VALUE GOODS REQUIRING ENERGY- AND POLLUTION-INTENSIVE PRODUCTION

SPACE COLONIZATION

FIG. 4

NASA HQ MT76-1182 (1)
11-10-75

yield of 35%. There would thus be an improvement, i.e., profit margin, of 4½ to 1 over ground processed chips.

According to Western Electric Manufacturers Association (WEMA), the market for ICs in the free world was on the order of $5 billion in 1975, with $6 billion predicted for 1977. Extrapolation leads to an annual average of $19 billion between 1985 and 1989. The share of silicon, as raw material, in this market is estimated at about 10%.

Among the space-manufactured metals of interest are materials for high-strength permanent magnets, turbine blades, and X-ray targets.

Even more important will be separation and culture-growth processes of biological products such as pancreatic cells (insulin), pituitory cells, edothelial cells (macrophages), bone marrow, blood cells (lymphocytes, granulocytes), sperm cells (control of sex in farm animals), and enzymes. Space-processed biologicals include the enzyme urokinase with the potential of preventing up to 50,000 deaths per year in the U.S. due to thromboembolisms (blood clots), and erythropoietin for the treatment of kidney failure and anemia. In the U.S. alone, the annual requirements for urokinase are 500,000 doses at an Earth-produced cost of $2.5 billion. If produced from space-

enriched material, the cost would amount to only $400 million (Reference 9).

Similar considerations apply to space-processed lymphocytes (for prevention of organ transplant rejection) and macrophages (for early detection of immunological reaction).

PUBLIC SERVICES. Basic concepts of making space useful and directly relevant in the everyday life of large numbers of ordinary citizens involve the placing of very large satellites and antenna structures into orbit.

In a reversal of a previous space flight principle which required that spacecraft be kept as simple, light-weight and reliable as possible by relegating functions associated with complexity and weight to ground stations, the achievement of easy access to and from space and permanent occupancy of space by people will permit us to develop and operate large and complex satellites.

NASA studies indicate that in many applications of information transfer minimum total system cost might be achieved by deliberately making satellites large and highly capable, accepting their expense in order to allow

the user equipment to be tiny, highly portable, and inexpensive. Because of the vantage point of geosynchronous altitude, millions of Earth-based users can be serviced by one or only a few satellites, and the cost of even very large and capable satellites and antennas could be expected to be less than that of the terminals, resulting in minimum total cost while simultaneously performing functions of unprecedented system utility not possible with simpler and smaller satellites. By using people in space for assembling, maintaining and servicing advanced systems of this type, these satellites can reach very large size. Due to the weightlessness of space, however, the erection and assembly of large antennas and reflector structures will not be subject to the constraints of weight deflections. Typical active multi-beam antennas for RF and microwave output identified to date would measure 200 to 600 feet in diameter and operate at power levels of 20-150 kW. Passive space reflectors for beaming light to Earth or relaying energy can reach diameters of 1000 to 3000 feet (Reference 10). Space power collectors may measure miles in length and width, as stated before.

The new, almost unlimited opportunities offered by space communications using these advanced systems have the potential to answer many serious needs of mankind in

numerous personal, civic, government, industrial, and international applications in the next 25 years and beyond.

For improved personal communications, for example, a single 200-ft satellite could service 2,500,000 people with two-way voice and data communications, using ground user radio sets no larger than a "Dick Tracy" wristwatch radio. For improving mail communications, a multi-beam satellite with total U.S. coverage may relay up to 30% of U.S. mail electronically (100 billion pieces per year) and accrue cost savings on the order of $1 billion/year. Improved educational opportunities would become available with a large, high-power TV direct broadcast satellite bringing televised programs to mountainous, rural and remote areas of the world. Multi-beam satellites that provide citizens via wrist radio with around-the-clock access to police headquarters, and police with jam-proof communications from any location, will reduce crime rates. Improved public and governmental services could be obtained by using multi-beam satellites for direct and immediate communications to disaster areas as well as direct, instantaneous individual voting and polling. Intrusion detection of ships, personnel and goods across borders and coasts by large RF arrays in space, global communications

with ocean vessels via space-based low-frequency loop antennas, and 24 hr/all-weather monitoring of global air and ocean traffic with a large microwave antenna satellite could improve national security and international air/sea traffic lines (Reference 10).

To achieve these long-range goals in a practicable step-by-step "Push/Pull" development, Space Industrialization would make use of a Space Construction Base (FIG. 5) in the early 80's to (a) develop and demonstrate concept technology, (b) erect, assemble and test large structures in space, and (c) develop the first operational communications systems by transferring complexity from ground to space.

Early NASA studies of a Public Service Platform (PSP) indicate that integrated platform concepts with multiple functions may be superior to non-integrated separate satellites with dedicated antennas. A typical first stepping stone, by 1985, may be a demonstration antenna of about 2400 m^2 area and 7 kW of RF power in a 500 km orbit, with four different voice/data transmission functions. Subsequent growth to a 3-antenna platform with 13 functions (voice/data transmission functions, voice/video/imaging functions, and security/safety detection and control functions) and relocation from low Earth orbit

to geosynchronous altitude could be achieved as next step in 1986/87 (Reference 11).

6. NASA Studies

The total, overarching concept of Space Industrialization is currently becoming subject of intense study. These efforts, contracted with Rockwell International and Science Applications, Inc. (Reference 12), are primarily a planning activity intended to lay the necessary groundwork for subsequent implementation phases of a Space Industrialization program and the required support programs, including space transportation systems, domiciliary facilities in space, and space assembly/manufacturing facilities. Prime objective of these efforts is to develop an evolutionary Space Industrialization program which leads from Shuttle/Spacelab and early Space Station/Space Construction Base experiments to the permanent, practical and commercial utilization of space.

7. Summary

Space Industrialization has joined science and exploration as a major concept of space activity that introduces new themes of human space flight (FIG. 6).

NEW THEMES FOR MANNED SPACE FLIGHT

- ON-ORBIT EXPERIMENTATION, INSTRUMENT DEVELOPMENT, SERVICING & MAINTENANCE
  - PRODUCTION AND MANAGEMENT OF FOOD AND FORESTRY RESOURCES
  - PREDICTION AND PROTECTION OF THE ENVIRONMENT
  - PROTECTION OF LIFE AND PROPERTY
  - ENERGY AND MINERAL EXPLORATION
  - TRANSFER OF INFORMATION
- SPACE ASSEMBLY, CHECKOUT, EMPLACEMENT, AND SERVICING OF LARGE STRUCTURES
  - SOLAR POWER CONVERSION AND TRANSMISSION
  - TERRESTRIAL POWER RELAY
  - SPACE LIGHT ILLUMINATION
  - RADIO-ASTRONOMY
  - AID TO CIVIL PROBLEMS (OBSERVATIONS. COMMUNICATIONS, SUPPORT SERVICES)
- SCIENTIFIC AND COMMERCIAL UTILIZATION OF SPACE
  - BASIC PHYSICS AND CHEMISTRY
  - MATERIAL SCIENCE
  - COMMERCIAL INORGANIC PROCESSING AND MANUFACTURING
  - PRODUCTION/ISOLATION OF BIOLOGICALS (e.g., BLOOD CELLS, VACCINES, INSECTIDES)
  - EFFECTS OF GRAVITY ON TERRESTRIAL LIFE
  - MAN LIVING AND WORKING IN SPACE
  - PHYSIOLOGY AND DISEASE PROCESSES
- STEPPING STONES FOR FUTURE HUMAN NEEDS AND OBJECTIVES
  - IMPROVEMENT OF TECHNOLOGY/CAPABILITY (TRANSPORTATION, HABITATION, OPERATION)
  - DEVELOPMENT OF CLOSED ECOLOGY SYSTEMS (SPACE-BASED AGRICULTURE, ATMOSPHERES)
  - DEVELOPMENT OF HUMAN PHYSIOLOGICAL ADAPTATION TO SPACE
  - ACCESS TO EXTRATERRESTRIAL RAW MATERIALS AND ENERGY
    - SPACE INDUSTRIALIZATION
    - OCCUPATION AND SETTLEMENT OF THE MOON
    - COLONIES IN SPACE
    - MANNED MARS EXPLORATION
    - HUMAN EXPLORATION OF THE SOLAR SYSTEM
    - INTERSTELLAR FLIGHT

FIG. 6

In mankind's long-range drive to humanize space and achieve eventual space colonization, the industrialization of space can offer a realistic approach to developing a progressive program to provide permanent, practical and commercial utilization/tools of space through products and services that create - in the long run - new values, jobs, and better quality of life for all mankind.

The planning of such massive space endeavors as space colonization in the far future is quite helpful since it enables us to trace possible pathways of "Push/Pull"-type development through Space Industrialization back to the present. In thus establishing a "relevance tree" (FIG. 7) between far-future "dreams" and near-term realities and "pragmatisms", we are in a better position to identify major stepping stones which are useful to mankind in terms of contemporary benefits (short-term returns) while at the same time being relevant to future growth-type needs. Once these vectors are established, we do not have to be too specific about the actual far-future goals and can leave their selection up to our future generations.

EVOLUTIONARY PATHS TO FAR-FUTURE SPACE ENDEAVORS
(Relevance Tree)

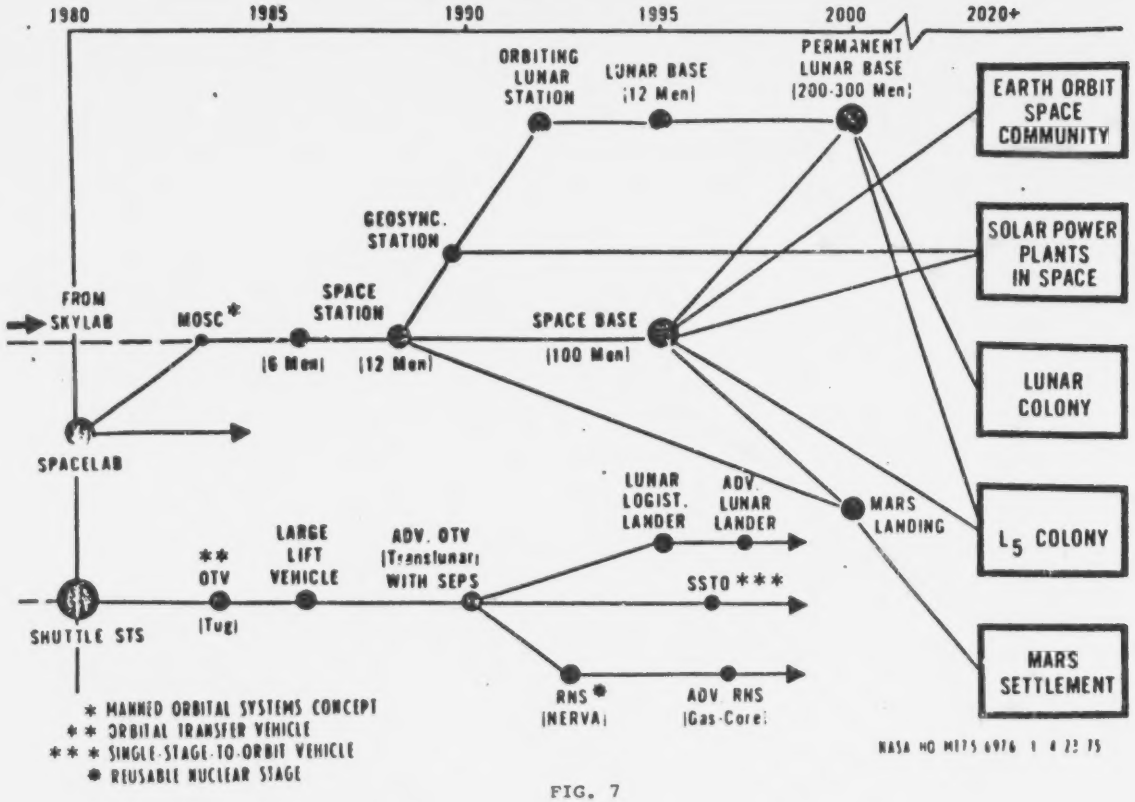

FIG. 7

This approach brings "dreams" into the realm of "strategic" thinking. It allows us to (1) give a larger purpose to our near-term "tactical" and pragmatic activities and thus re-introduce the "dream" in our "Now"-orientation, and (2) improve our ability to avoid dead-end "branches" in our major planning decisions for Space Industrialization.

The merits of Space Industrialization lie in the fact that they encompass all human beings. This is a new fundamental premise, untenable without highly developed industrial foundations. Knowledge, health care, and the satisfaction of other existential and higher needs no longer are privileges of a few but fundamental rights of all. While space colonization, if taken as initial goal and prime objective, would probably "benefit" only a relatively small group of people living in a space colony, Space Industrialization can benefit <u>all</u> people on Earth. Moreover, it would not preclude but in fact validate the option that the industrialization of space may subsequently grow into space colonization as full self-sufficiency in space is reached. By being basically non-elitist, Space Industrialization will thus introduce the true humanization of space.

FOREWORD

This $198,962.00 Space Industrialization Study was performed under NASA Contract NAS8-32197 for Marshall Space Flight Center from September 1976 through April 1978. The study was in two parts: Part 1 identified the future opportunities for space industrialization, quantified the potential benefits and developed and analyzed evolutionary program options required to take advantage of these opportunities; Part 2 defined the framework of international governmental, industrial, legal and economic constraints within which space industrialization (SI) must evolve. Step-by-step guidelines to implementation of programs to capitalize on the SI opportunities were formulated using information from Part 1 and Part 2. The study results are documented in four volumes:

1. SPACE INDUSTRIALIZATION - AN OVERVIEW
2. SPACE INDUSTRIALIZATION - OPPORTUNITIES, MARKETS AND PROGRAMS
3. SPACE INDUSTRIALIZATION - WORLD AND DOMESTIC IMPLICATIONS
4. APPENDICES

Part 1 of the study was managed by Dr. Ralph Sklarew and Part 2 by Mr. Gerald W. Driggers. Other key SAI participants were Mr. E. Battison, Mr. D. Davis, Mr. Sam Gibson, Mr. Mark Klan and Mr. Gordon Collyer. A large portion of the work reported here was accomplished by consultants who occupied roles as principal investigators. The key consultants were:

- Mr. Robert Salkeld - System Planning and Programmatics
- Mr. G. Harry Stine - Industrial Planning and Marketing
- Mr. Paul Siegler - Market Assessment and Economic Analysis
- Dr. J. Peter Vajk - World Dynamics and Futures Assessment

A subcontract to Southern Research Institute (SoRI) in Birmingham, Alabama, was managed by Mr. Driggers during Part 1 of the study, prior to his joining SAI. Key participants at SoRI were Mr. S. J. Causey and Mr. R. Monroe.

Certain individuals within, and with no affiliation to SAI, provided valuable informal data, comments and guidance during the study. The following are recognized for their special contributions.

- W. E. Zisch
- G. Hergert
- Coultas Pears
- F. C. Durant III
- Dr. Jerry Grey
- Dr. G. A. Hazelrigg
- B. A. Schriever
- T. F. Walkowicz

- Frederick Ferber
- Mark Frazier
- Katherine D. Hallgarten
- George Koopman
- Hans Wuenscher
- Daniel Cassedy
- Theodore Taylor
- Donna Klan
- Dr. Marta Cehelsky
- Dr. Peter Glaser

The interchange of ideas and concepts provided by technical and informal meetings with Mr. C. L. Gould and Mr. A. D. Kazanowski of Rockwell International during Part 2 of the study is also gratefully acknowledged.

The study was performed under the technical direction of Mr. Rodney Bradford (Part 1) and Mr. Georg von Tiesenhausen (Part 2), Marshall Space Flight Center. Mr. J. von Puttkamer was the program manager for NASA Headquarters, Office of Space Transportation Systems.

Inquiries regarding the study should be addressed to the following:

1. SUMMARY

Space Industrialization (SI) is the medium by which services, energy and products are returned from space to Earth to provide economic and other pragmatic benefits to mankind. Although this study focuses on the United States as the mechanism for benefit generation and transfer (with an appropriate payback to its industry and citizenry for investing resources and labor), it is the world that benefits. Indeed, the underdeveloped and developing countries are now, and will continue to be, prime beneficiaries from Space Industrialization. It is possible to construct credible scenarios which step these nations into the twentieth century equivalent of the U.S. in less than 100 years, without significant local or global economic or environmental damage. The great power for what is considered "good" in the western world (health, safety, knowledge, creative growth, etc.) afforded by Space Industrialization has been comprehended by a very few, but there is evidence that realization is spreading. It is hoped that this document and this report, in conjunction with the companion report by Rockwell International, will assist in this realization, and help promote early expansion of the beneficial returns on humanity's investment in space.

The SAI study concentrated on the U.S. and what we may gain from the investing of our resources, both public and private, in SI. The future was examined to characterize resource pressures, requirements and supply (population, energy, materials, food); also, the backdrop of probable events, attitudes and trends against which SI will evolve were postulated. The opportunities for space industry that would bring benefits to Earth were compiled and screened against terrestrial alternatives. Most survived, and a population of the survivors were examined to determine if SI would ever be "worth the investment". A cursory market survey was conducted for the selected services and products provided by these initiatives and the results were astounding. Space Industrialization is a billion dollar a year business now; in thirty years it could grow by 100 times that amount or more!

But, space is expensive. Might not the investment outweigh the gain? Programs of SI evolution corresponding to the postulated future scenarios were developed, and the investments compared to the revenues and their associated benefits. The program analysis results brought two observations: SI investments will be good investments and the sooner the investment, the better for all concerned (in terms of the pure mathematics). It was recognized, however, that certain other factors may control the practical rate of progress.

These "other factors" were examined to the extent practical in this study; a great deal remains to be done. The following observations are in order, however, based on this assessment.

(1) Foreign competition is becoming very strong in SI. It is no longer "our" domain and these pressures will increase. This may limit or spur U.S. increased involvement.

(2) The developing and underdeveloped nations of the world may consider the U.S. and SI a threat or a powerful tool for progress depending on how we promote it.

(3) Prospects for economic return to the government (public sector) are excellent, so long term investments should be justifiable. A few billion of dollars invested in the eighties will result in hundreds of billions in tax revenues, millions of jobs created, strong economic growth and good balance of trade impact in twenty years or less.

(4) Although some U.S. industry will resist SI, a strong support base can be built among U.S. private enterprise.

(5) In both domestic and international law there are no legal entanglements which will seriously inhibit SI development, if we develop proper policies and stick to them!

(6) Although many social and political institutions will be affected by SI, the most significant are those institutions governing industry and government relations and those relating the U.S. to the rest of the world. Nothing precludes mutually beneficial arrangements in both of these arenas. Historically, such arrangements have taken several years to evolve.

(7) The most important SI initiatives would appear to have rather high initial investments, and payback periods longer than normal for private investment. A mechanism for reducing initial risk and shortening these payback times is possible and will attract substantial industry support upon initiation.

Thus, in sum, this study has concluded that Space Industrialization exists and substantial and sustained growth is highly desirable. From examination of the SI programs and their characteristics the following recommendations were drawn.

(1) Strong industry involvement in all areas of SI from planning to ultimate operations is necessary to return maximum benefits.

(2) A central group, perhaps under the Administrator of NASA, especially tasked to plan, integrate and advocate SI activities is needed badly. Such a group, located within the government, may indeed be essential if private enterprise can not meet the challenge on its own.

(3) Space Industries will need 25 to 75 KW of raw power in the early-to-mid-eighties, 100 to 500 KW in the latter eighties and 1-10 MW in the early to mid-nineties. A Solar Power Satellite prototype development program to prove technical/economic feasibility and environmental acceptability would have similar milestones and characteristics. Space power needs for products have a similar progression, with the possibility of a three to five year lag in demand relative to other requirements. A space power program designed to integrate and synergize these requirements should be initiated, beginning with development of the 25 KW Power Module currently proposed. The requirements for a concurrent large structures program is implicit to the power program.

(4) The cost of space transportation to low Earth orbit must come down below shuttle projections by a factor of 10 to 100 to really open the products market in the nineties. The Shuttle is the key, but the longer term SI requirements are already apparent. Increases in flexibility and decreases in cost are needed by high orbit operations in the latter eighties for both services and energy initiatives. Propulsion and vehicle programs to meet these needs should be integrated into future transportation planning.

(5) The U.S. (probably through the NASA) should embark on an intensive data gathering and planning effort during FY 79, 80 and 81 in parallel to initiation of early projects such as 25 KW Power Module. This effort would culminate in a carefully coordinated, evolutionary Space Industrialization Plan with domestic and international as well as government and industry segments.

The above recommendations imply only modest budget commitments over the next three years (less than five million per year in studies and planning and less than fifty million per year in hardware commitments). The budget requirements for development and implementation of initiatives with early direct returns (mid to late eighties) plus long lead technology development for the nineties has a funding peak of less than four billion dollars annual. That cost could be shared in various ways between NASA, other government agencies, private industry and international (or foreign) organizations. The space technology peculiar funding requirements are less than two billion of the four billion total.

A great deal of work remains before Space Industrialization enters the main stream of government and industry planning, and a proper public understanding is achieved. A solid information base, a dedicated advocacy group and very hard work are the essential ingredients to accomplishing these objectives. The rewards will be worth the effort, and attaining these goals will turn Space Industrialization into the mechanism for achieving the next plateau of human development.

The remainder of this document provides discussion in greater depth in the tasks of the study as outlined in the Summary. Volumes 2, 3 and 4 of this report contain the in-depth discussion and data.

2. THE TERRESTRIAL BACKGROUND FOR SPACE INDUSTRIALIZATION 1980 - 2010

During the next few decades, space technology (developed for purely scientific reasons, for political and prestige reasons, or to serve specific military needs) can be adapted, extended, and expanded to use the new environment and nearly limitless resources of outer space for the benefit of humanity in an economically profitable manner. Space industrialization will then grow from a handful of commercially operated communications satellites into a highly diversified and expanding sector of the human socioeconomic system. In the first few decades, however, it will necessarily depend for its very existence on the conventional segments of the socioeconomic system to provide the technology, the original investment capital, and the markets for its goods and services. Thus it is essential to explore the nature and shape of the socioeconomic system as it may evolve in the next few decades before we can realistically examine just what may constitute space industrialization, and how, why, and when portions of the new space industries may arise.

This examination of the terrestrial background has been done in two parts. First, basic macroeconomic projections were made to examine the needs of the human socioeconomic system during the coming decades with respect to basic materials: energy fuels, minerals, and basic agricultural commodities. If the "limits to growth" hypothesis should prove to be correct, then perhaps space industrialization could provide some of the very basic needs of the industrialized societies of the world. Second, a variety of alternative futures were examined to determine how space industrialization might be shaped by events and developments in the rest of the system. The economic profitability, political viability, and social desirability of specific space industrial activities can only be defined in the context of general social, political, economic, and technological factors characterizing an alternative future. These alternative future scenarios also provide some basis for contingency planning and for identifying stepping stones in space technology which are most likely to be useful in any future space programs or activities.

The results of these two parts of our examination of the terrestrial background provided some of the basis for considering the market potentials of various possible space industries and much of the foundation for developing specific examples of possible programs of space industrialization during the next few decades. The necessity for continuous planning of intermediate and long range programs became quite clear from this work. Just as buggywhip manufacturers who did not foresee that self-propelled trucks would make the horse-drawn milkwagon obsolete were soon reduced to financial ruin, proponents of specific possibilities for industries in space may find themselves stranded by changes in the terrestrial background due to new economic, political, social, or technological factors unless they continually dedicate some effort to planning their programs in relation to current developments and trends on Earth.

2.1 RESOURCES ASSESSMENTS

A detailed assessment (case-by-case) of natural resource availability (described in Vol. 2) was made for 18 minerals selected either because of their large volume (such as iron) or because of critical importance to important industrial processes or agriculture (such as phosphate). Fossil fuels were also examined in assessing likely sources of energy in the next three decades. But to assess supply and demand for such commodities, it was necessary to project population growth and trends in basic economic indicators such as GNP and personal incomes. In addition, we have examined the outlook for a number of basic agricultural commodities, albeit in a somewhat simplistic manner.

2.1.1 Conclusions

It does not appear, on the basis of our examination of energy, minerals, and food production issues over the period 1980 to 2010, that any of these will pose any critical threat to the survival of industrial civilization. The spectre of impending scarcities does not, therefore, provide a credible basis for the political support necessary to mount a major thrust into space at public expense on a crash program schedule. The importance of long-range solutions to the problems of energy supply, however, is clear in the discussion above. The economic value of energy

and minerals imported from space may be significant and may provide sufficient motivations for space industrialization; these possibilities should not be dismissed lightly. But their justification, during the period of interest in this study, must be found elsewhere. "Limits to growth" cannot justify space industrialization during the next three or more decades.

2.2 CONSTRUCTION OF ALTERNATIVE SCENARIOS

We have selected a list of ten events or developments which appear to have a reasonable chance of occurring in the next two or three decades and which would be likely to have major effects on the shape of the future. Arranged according to morphological categories, these "triggering" events or developments are as follows:

Extrapolative:

Baseline (for comparison-no "triggering events")

Political:

Major advances in space by other nations.
U.S. commitment to space.

Societal:

Major breakthrough in human longevity.
U.S. disenchantment with space.

Economic:

Entrepreneurial exploitation of space technologies.
Artificial shortages of critical minerals.
Economic collapse due to shortage of capital.

Technological:

Breakthrough in a new energy source.

Environmental:

Human-generated ecological catastrophies.
Rapid cooling of the Northern Hemisphere.

2.2.1 General Observations

The scenarios described here span a wide range of possible futures. While opportunities for the advocacy of a variety of specific space industrialization activities appear in every scenario, many of these opportunities are apt to fall in the private sector rather than in NASA

or other governmental agencies. Because of the strong possibilities of synergisms between various space activities, however, NASA can no more ignore private sector activities and developments than the private sector can ignore NASA plans for development of new launch vehicles. If NASA's efforts are to have the greatest benefit, these efforts must be based on up-to-date understanding of the opportunities for advocacy presented to the private sector and to the whole public sector by developments in the human system as a whole. This requires continuous examination by NASA of the changing opportunities and of the changing fabric of the human system. Planning space industrialization cannot be done effectively if it is done only in fits and starts; the volatility of the human system requires reassessment of alternative futures on a continuing basis to identify, at each moment, what space systems and space technologies are most likely to be used by a wide variety of space industrialization opportunities. Just as short-range planning is done on a continuing, day-to-day basis, mid-and long-range planning must be done continuously to prepare for contingencies.

3. INDUSTRIAL OPPORTUNITIES IN SPACE

The establishment of future markets and a space industrialization program for each future scenario required a compilation of potential opportunities. These were established to a level of detail and breadth of application sufficient to allow gross market survey and preliminary program formulation.

The purpose of this compilation was not to create an exhaustive shopping list of opportunities but rather to key in certain indicative possibilities within each industrial activity identified (Information Services, Energy, Products, People). The goal was of sufficient breadth to insure represensative program formulation and appropriate market survey. The result of this is a compilation of over 200 potential applications for space related goods and services.

As previously noted, the opportunities and their identified representative usage were compiled under four industry activity categories: Information Services, Energy, Products and People (in space). Each of these categories was further subdivided into subcategories as follows.

Information Services	Energy
Communications	Solar Power Satellite
Observations	Redirected Isolation
Navigation	Nuclear Waste Disposal
Location	Nuclear Power/Breeder Satellite
Sensor Polling	Power Relay

Products	People
Biologicals	Tourism
Electronics	Medical
Electrical	Entertainment/Art
Structural	Recreation
Process	Education
Opticals	Support

4. THE TERRESTRIAL ALTERNATIVES

Thirty-two candidates for space utilization were compared to potential Earth based alternatives. Comparisons were based on examining the initial cost of installation on a first order basis and a cursory review of qualitative factors such as ease of use, reliability, technology requirements, etc. If costs and capability obtained appeared comparable between the alternatives, they were retained for further study. In certain instances the identified space uses exhibited much lower cost for similar capability or the reverse. These were identified as clearly viable candidates. Where cost and/or capability were clearly superior for the Earth alternative, the candidate was dropped from further consideration.

For five of the thirty-two the terrestrial alternative was deemed clearly superior, seven appeared more favorable accomplished from space and twenty depended too much on specific details (too close to call).

The generic lessons culminate with the conclusion that alternatives do exist, or can be visualized for most space initiatives. "Uniqueness" of the space candidates detailed was not deemed strong enough to warrant special consideration in a competitive environment. Significant technological "lead" for space options was found only in the area of earth resources. And, in the case of communications, implementation may be tipped already toward terrestrial options. In concert with these arguments it is concluded that market softness, in terms of systems requirements, remove the constraint that terrestrial alternative systems must duplicate exactly space products and services.

The implications of the above statements gives rise to the following observations on the viability of terrestrial alternatives.

1) Complexity from detailed assessment of non-cost issues substantially reduces the opportunity to develop a "winning" mix of space efforts based on generalized benefits.
2) In lieu of a mandate, space viability must be aggressively advocated/studied against competitors in the mid 1980's.

3) The current involvement of an existing industry will typically indicate which alternative would be favored by it unless forced by competition to change directions. New entries in an industry will select a path based on investment and risk considerations. Most space initiatives considered in this study will appear highly favorable over terrestrial alternatives only after steps toward risk reduction are implemented.

5. POTENTIAL MARKETS AND REVENUES

5.1 APPROACH

After compilation of the list of Industrial Opportunities was complete, a review process was undertaken to select initiatives for preliminary market analysis. The primary criteria applied in the screening process were availability of data and probable advantage over terrestrial competitors. Assumptions were made based on the data available after the analysis was underway.

Different specific methodologies were applied according to which industry was being examined. For example, market analyses for Products were much more speculative than those for Information Services since much less is known about the specific use and probable cost of a prospective product. A common set of general methodology guidelines were used wherever appropriate and provide the foundation for understanding the philosophy and assumptions which guided these market surveys.

5.2 AGGREGATION OF MARKET POTENTIAL

One conclusion quickly drawn from the data derived in these analyses is that very large single opportunity revenues are possible in several areas. It follows that aggregates of these potential (or expanded) industries will represent even great possibilities.

As indicated in each market analysis the flow of revenues initiates and evolves based on several assumptions including best case/least case for total market potential at saturation. Thus the actual revenues which might be anticipated in the time period of this study will depend substantially on the background scenarios previously presented. For purposes of analyzing far and near term implications of space industrialization, the time frame of initiation and rate of growth of each industry was adjusted during the analysis.

Although the more exact figures will depend on such specifics as future scenarios and programmatics, it is worthwhile to summarize revenue projections. This will allow interpretation by the reader of the

possible significant of SI in the 1980 - 2010 time period. Summary data are presented below for revenues (best case). The timing shown is considered to correspond roughly to the baseline scenario. All revenues calculated are additive to current SI revenues which total about one billion dollars per year in 1978.

The relative value of each market area (Information Services, Energy, Products and People) as a function of time is presented in Figure 5-1. A more aggressive scenario (implying more aggressive SI programs) basically accelerates the revenue flow and adds more minor initiatives. A scenario without SPS eliminates that portion of the summary and inhibits other activities in the Information Services and Products industries. In the opinion of the SAI study team, given no "surprises", no substantial foreign challenges in space, etc., we can expect space industrialization to evolve as depicted in Figure 5-1.

Inherent to this prediction is a period of capability and technology development in the 1980s leading to expanded exploitation and utilization in the 1990s and intensive growth beyond the year 2000. The resulting interpretation from this is that revenues will approximately double from 1980 to 1990. A very rapid growth in revenue then ensues as technology and hardware development efforts in the eighties come on line in the 1990 to 1995 time period. Although new technologies (particularly in power, structures and transportation) are emerging, the activities settle basically into an implementation and expansion phase with doubling time for revenues becoming approximately five years until the end of the time period of interest.

There appear to be no "natural laws" or technological barriers which would limit revenue growth to the level indicated. Strong response to a foreign challenge or a heavy entrepreneurial initiative in the near future (early eighties) could result in more rapid growth. Potential revenues well over 100 billion (1977) dollars per year appear feasible with technology and development effort acceleration and aggressive marketing.

PROJECTED ANNUAL AND CUMULATIVE REVENUE POTENTIAL FOR SELECTED INFORMATION SERVICES INITIATIVES (1977 DOLLARS)

	POTENTIAL REVENUES (in Millions of Dollars)	
	ANNUAL (PEAK)	CUMULATIVE (1985 - 2010)

Figure 5-1. Project Revenues for Space Industry Activities Assuming the Baseline Scenario for Terrestrial Background

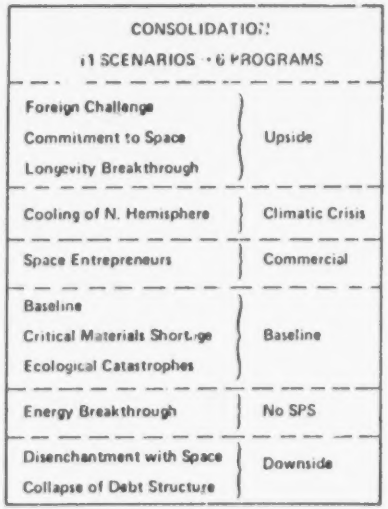
6. SPACE INDUSTRY PROGRAM DERIVATION AND ANALYSIS

The results of the work described in previous sections (Terrestrial Background, Opportunities and Markets) provided the basic information necessary to map out probable courses of future programs. Space Industrialization by definition consists of a multitude of development or operational programs occurring simultaneously or in series. In the first part (Part 1) of this study, the totality of programs was referred to as a "program" for convenience. That terminology has been maintained in this volume in order to distinguish these "program" analyses from the work in Part 2 of the study. In Part 2, SAI and Rockwell Inc. agreed to change the semantics so that the word "Plan" represented the totality of programs.

The flow and interrelationship of various tasks from which programs were derived and analyzed is shown on Figure 6-1 which also summarizes the grouping of eleven scenarios into six programs. The philosophy of this grouping is discussed in Volume 2.

The hypothetical programs we have developed reflect our considered collective judgment of what kinds of space activities are likely to be economically and politically viable in the assumed contexts of the background scenarios. Like the scenarios themselves, these programs should not be interpreted as attempts to forecast the future but rather as explorations of plausible alternatives which can be used to provide reasonable guidelines for long-range planning. This kind of exploration can serve to identify stepping stones which are common to a multitude of alternative futures and to identify systems which are likely to be much more dependent on external contingencies, requiring more careful attention to the course of events.

To scope future costs, impacts and requirements, three programs were selected for detailed analysis. These were the Baseline, No SPS and Upside Programs. The procedure was to take the general programs and just specific timing and scale according to guidelines from the scenarios



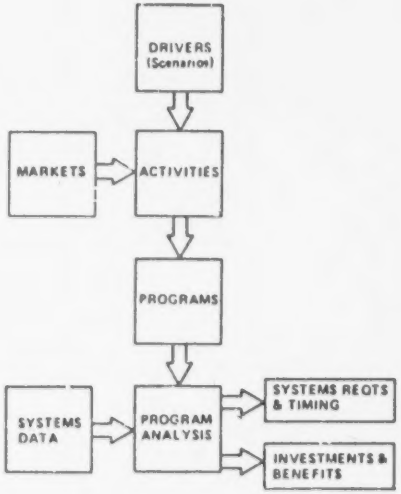


Figure 6-1. Summary of Space Industry Programs Derived and the Steps to Their Derivation and Analysis

and market data. In some cases several initiatives were lumped into a single system for purposes of simplifying costing and scheduling. A platform approach to developing the communications initiatives was assumed.

Introduction and growth of the various Information Services leads to requirements for very large platforms in the nineties and beyond corresponding to the market projections presented previously. This turned out to be the largest single set of industry initiatives in terms of power and structures other than SPS and light reflectors.

The results of the program analysis in terms of structure, power and transportation needs is shown in Figures 6-2 and 6-3.

ACTIVITY	INFORMATION	ENERGY	MATERIALS	PEOPLE
MAJOR SPACE ADVANTAGE	• VIEW • ACCESS	• SOLAR FLUX	• LOW 'G' HIGH VAC • HIGH VAC	• UNIQUENESS
MAJOR TECHNICAL HURDLES	• SIZE 10–100 METER ANTENNA • POWER 21 KW – 10,000 KW • DATA PROC • TRANSPORT COST (OPERATIONS)	• SIZE/MASS OF SYSTEM ~ 10^4 MW ~ 10^5 TONS ~ 10^{10} • TRANSPORT COST < $20/LB LEO • ENVIRONMENT ISSUES	• PROOF OF THEORY • PRODUCTION DEVELOPMENT HUNDREDS OF POUNDS PER DAY • POWER 10 KW – 10,000 KW CONTINUOUS • TRANSPORT COST < $100/LB LEO	• TRANSPORT COST $25/LB OR LESS • HABITATION

7. WORLDWIDE ACTIVITIES IN SPACE INDUSTRIALIZATION AND THEIR IMPLICATIONS

From military and scientific beginnings some twenty years ago (October 1957 for Sputnik, January 1958 for Explorer) there has evolved a broad and complex industrial base in space. The activities range from basic research in the space processing of materials to the fully operational information transfer systems. The worldwide gross annual revenue now exceeds one billion dollars in sales of services alone. Current published projections indicate that revenues from services by 2010 may reach ten to twenty billion dollars given only minor extrapolations of present technology. With technology advancements in power, structures, transportation, materials processing, frequency use and data handling our study indicates that the potential can be several times that revenue amount. Of the four general categories of space industrialization (Information Services, Products, Energy, People in Space) the area nearest maturity is Information Services. New technologies will be necessary to open up new markets in these services also, however.

The worldwide interest in SI is reflected by the number of countries and agencies that are actively participating at present. This is characterized in Figure 7-1 by summarizing capabilities both previously demonstrated and currently being developed that relate specifically to Space Industrialization.

Why is there such extensive involvement in organizing for and implementing Space Industrialization in the world? In the simplest terms, it appears that needs and markets exist forming the basis for large scale international involvements. This has prompted a wide spread interest and desire for independent capabilities to utilize space and an awareness of the potential benefits from gaining and maintaining a competitive position. In the free world the US will be challenged through the eighties in all technologies including those that are peculiar to manned space flight. The recent capability demonstrations of the USS aboard Salyut 6 and the strong reports of their current development of a reusable shuttle leave no doubt that major technical achievements can be anticipated by communist bloc countries in SI throughout the eighties.

Figure 7-1. Worldwide SI Capability Summary

8. DOMESTIC IMPACTS AND ISSUES

Space Industrialization (SI) will have impact and meaning in many areas of human endeavor in the United States as well as the world. These impacts may be more subtle than profound, given the level of economic and technical development already enjoyed by the U.S. Nonetheless, these impacts will be important and, indeed, can provide the stimuli necessary to assure U.S. economic growth through the last decade of this century and into the next. The realization of these impacts in a positive fashion will depend completely on establishment of government roles supportive to greatly enhanced private sector involvement in space.

8.1 EMPLOYMENT AND ECONOMY IMPACTS

The economic impacts examined in this study were based on an alternate approach to simple trend extrapolation. From the scenario, market and program work reported in Volume 2, it was surmised that significant opportunities existed in the near future in the public and private sector. If advantage is taken of these opportunities, a much greater benefit to the U.S. and world can be realized than would be predicted by simple trend forecasting. Thus the analyses whose results are presented here were structured to show what could happen, and hopefully help precipitate the required actions. As mentioned in the discussion on Future Scenarios (Volume 2), an implicit assumption in all analyses was that opportunities would be capitalized on, the extent of which varied between scenarios. This is reflected in the six programs developed and presented in Volume 2 and more specifically in the two programs analyzed in detail. The following benefit calculations are based on those analyses.

8.1.1 Assumptions

Certain assumptions concerning the nature of the industries involved in stimulating and handling the revenue flows were necessary. Composite indices were developed and applied across the board without specific variation between industry types, products vs. services, etc.

Given the composite nature of the expenditures and revenues on a whole program basis and our uncertainties, even detailed indices would yield aggregate approximations. Thus a more detailed industry-by-industry assessment is not warranted until more specific analyses are performed on the projected revenues and costs.

The specific indices used were:

$$\frac{\text{BEFORE TAX PROFIT}}{\text{GROSS REVENUE}} = 0.20$$

TAX BRACKET = 0.50

LABOR INTENSITY (OPERATIONS AND MAINTENANCE) = 0.40

COMPOSITE MEAN SALARY = $17,000 ANNUAL

These figures are typical of various service industries today subject to government regulation. Although profit margin for COMSAT was somewhat higher in the past, the trend has been to force it downward. As discussed in Section 6 of Volume 3, after tax profits have varied from six to fifteen percent typically.

Current corporate taxes are 49 percent. For simplicity, a straight 50 percent was used.

Calculations were performed for two points in time. First, 1985 was selected as a representative near term year where almost all new revenue in SI would be investments. This was assumed to be almost purely public funding (government sponsored development programs). The latter year chosen was 2010, the end of the time period being examined (1980-2010). The revenue in 2010 is projected to result almost entirely (>95%) from sales of Services, Products and Energy (People in Space revenues are insignificant compared to the others).

8.1.2 Results

Jobs and taxes generated were estimated for three programs: the Energy Breakthrough (No SPS), the Baseline (with SPS), and the Upside (all initiatives). Although the Upside is considered the least likely of the three (requiring heavy investment in the early eighties), it was desirable to assess the potential impact of such a strong,

aggressive set of initiatives. The results were as follows:
(For comparison with the companion Rockwell International report on SI, the NO SPS corresponds to Plan C, BASELINE to Plan A. An UPSIDE type program was not addressed by RI.)

	NEW JOBS*		
	NO SPS	BASELINE	UPSIDE
1985	15,000	100,000	120,000
2010	1,000,000	1,900,000	3,800,000

	TAXES GENERATED*		
	NO SPS	BASELINE	UPSIDE
1985	$ 100M	$ 800M	$ 1000M
2010	$10,000M	$ 20,000M	$40,000M

* DIRECT ONLY. U.S. MARKETS ONLY

The estimate of jobs for 1985 is probably low by a factor of two since most funding would be to the aerospace industries. The Aerospace Industries Association (AIA) has estimated that about 30 direct jobs are created for each one million dollars of appropriation. Direct plus indirect jobs are estimated to total about 100 jobs per one million dollars. Thus the job projection for 1985 is conservative since the computation was the same as for 2010. The true impact on new jobs is some two to four times the numbers shown here depending on specific assumptions and economic theory applied.

In the aggregate, the best guess is that 75% or more of the postulated SI initatives revenues will be job creating in the nineties and beyond. Thus for a workforce of 100,000,000 in 2010 some three to twelve percent could be employed in new jobs created by space industrialization.

The tax revenue calculations take into account corporate taxes based on previous assumptions plus personal income taxes of direct employees. A national composite rate of 0.26 for federal and state income tax was applied to personal income.

8.2 SAMPLE INDUSTRY COMMENTS AND RECOMMENDATIONS

Industry representatives involved in private enterprise in the three major categories (Information Services, Energy and Products) were contacted. The purpose was to obtain information on how government and industry could cooperate and complement in order to make space industrialization grow.

The contacts consisted of:

Information Services - two contacts in the satellite communications business.

Energy - two contacts in power R & D
- two contacts in the investment community

Products - nine contacts in non-aerospace manufacturing

At present a corporate leader/manager cannot justify any investment in products (at the basic research stage and having much too high transport costs) or energy (overwhelming techno-economic risk). The more expensive communications systems (such as the Orbital Antenna Farm of Morgan and Edelson, COMSAT) are being looked at rather seriously, although the total capital and payback times on larger systems look doubtful (see Section 6, Volume 3). One simple message is certain. As techno-economic risks come down, U.S. industry will steadily increase its allocation of resources to SI if a reasonable payback can be obtained. "Reasonable payback" will vary broadly based on initial investment, near term vs. long term risk, guarantees, etc.

8.2.1 Industry Views on Roles and Responsibilities

The specifics of appropriate roles and responsibilities which could be adopted by industry and government vary broadly according to the industry and the individual. It is possible, however, at the rather gross segregation level presented in Figure 8-1 to assemble a set of consensus opinions. As might be anticipated the communications industry is sufficiently mature that the Product Development and Pilot Operations areas require consideration of specific proposals to obtain a particular opinion. The large geo platform concept was one initiative that generally fell in the joint venture category

INDUSTRY IDEAS ON ROLES & RESPONSIBILITEIS

SAI4242

*DEPENDS ON SPECIFICS

Figure 8-1. Industry Views on Roles and Responsibilities

for example. A new version of an existing satellite system was considered to be an appropriate industry activity. Particular attention is drawn to the consensus or CEP blocks.

The information presented here is considered as a stage setting providing general guidelines for development of specific arrangement on a case by case basis. Early general agreement to these guidelines by government would encourage enhanced industry involvement in space industrialization.

Specific concerns and recommendations from industry were compiled into a rather extensive list. These are presented in Volume 3.

9. LEGAL CONSIDERATIONS

The legal considerations which must be recognized in any broad examination of space industrialization are, at first glimpse, staggering in their number and complexity. Entire symposia and extensive sessions during various astronautical conferences have been devoted to deliberations on interpretation of existing and proposed agreements, treaties, statutes, etc. In this study, there was no attempt to provide legal interpretations of laws and agreements. Instead, expert opinion was relied on to ascertain the answers to two simple questions: Are there any international laws or agreements which would preclude or severely limit evolution of any of the SI initiatives discussed in this study? Are there domestic laws (in the U.S.) with similar potential for limitation?

At present, space industrialization is not suffering substantially from either international or domestic legal constraints. The large scale initiatives discussed in this report for implementation in the 1980 - 2010 period could all be exercised today within the legal structure. However, all indications are that a series of initiatives to limit the U.S. and its industry are in existence or being originated. A net effect of these in the light of no established national policy in this arena will be to increase economic risk and foster impediment to industry involvement in SI. Without steps to assure industry in these matters, space industrialization may falter regardless of economic and technological enticements.

10. INSTITUTION IMPLICATIONS

A host of institutions ranging from religious to technological will be affected by space industrialization. Their influences on the growth of SI and the specific opportunities which will be capitalized on vary greatly, of course. From discussions with industry contacts, investors, lawyers and national politicians there emerged a basic set of considerations which form the back drop for detailed analysis of key institutional implications.

These items, termed "Five Significant Considerations", are:

1. Space industrialization must become an integral part of national space policy planning.
2. Industrializing organizations and legal structures must evolve and be encouraged.
3. Mechanisms for advantageous transfer of responsibility necessary.
4. The applicability of SI technologies to many problems, needs and markets will go unnoticed without focused dialog.
5. The knotty issues of today in technology export will be further driven by the international/multinational nature of SI.

The government/industry/academic institutional arrangements necessary to accomplish tasks 1 through 3 and optimize benefit from 4 and 5 must be designed in a fashion responsive to the needs of individual SI initiatives. The first steps can be taken, however, by establishing a planning office responsible for the integration of space industrialization elements into all national space activities and plans. This office could supply the data for decisions on items 4 and 5 and formulate plans and focus for accomplishing items 2 and 3 as well as continually project, monitor and assess the implications to a broad family of institutions. Such data should prove invaluable to government and private decision makers alike.

11. CAPITAL REQUIREMENTS AND ECONOMIC VIABILITY

From the revenue analyses reported in Volume 2 of this report it appeared that substantially increased interest in SI might be forthcoming in the investment community. Such interest would result not only from revenue potential but also from initial investment, cash flow, pay-back time, project rate of return and similar considerations. Although such analyses were desirable in all industrial areas considered (Information Services, Energy, Products and People in Space) certain limitations and pertinent factors had to be recognized. Specifically, the rapid developments in evaluations of the economics of space based power, the lack of detailed knowledge on product characteristics, and the dependence of People in Space activities on development of other industries precluded reasonable economic assessments in this study. Thus Information Services was the industrial area selected for assessment of these more detailed economic factors.

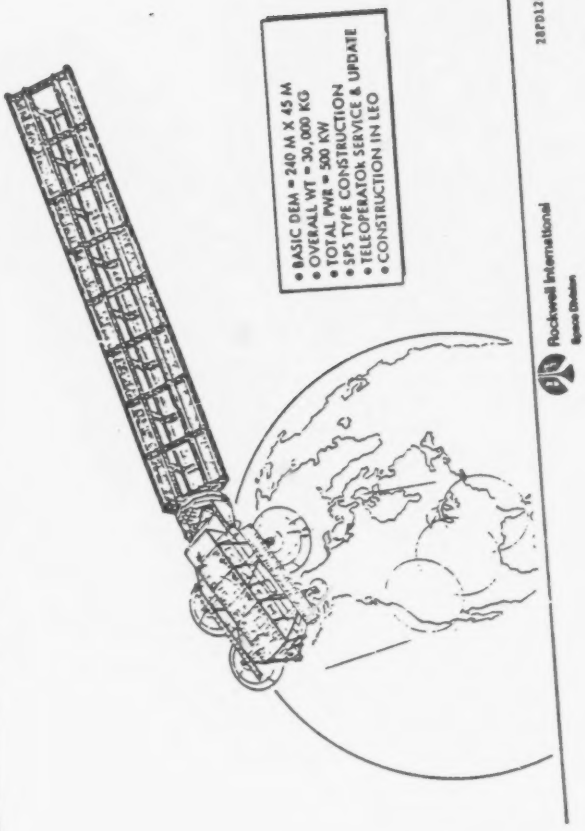
Five initiatives in Information Services represent over 90% of the potential domestic revenue from space in Information Services (see Section 5.8, Vol 2). These are:

1. Portable Telephone
2. Teleconferencing
3. National Information Service
4. Direct Broadcast TV
5. Electronic Mail

The large potential market for these services was taken as a natural indicator of private investment potential.

The first multi-use Geosynchronous Platform to provide market entry into the five services is shown in Figures 11-1 and 11-2 (courtesy of Rockwell International). This design provided the basis for development and initial operational cost assessment. As the markets develop into the 1990s and beyond, larger versions of the same type system were assumed.

The specific functions provided by this early satellite are as follows:



• BASIC DEM = 240 M X 45 M
• OVERALL WT = 30,000 KG
• TOTAL PWR = 500 KW
• SPS TYPE CONSTRUCTION
• TELEOPERATOR SERVICE & UPDATE
• CONSTRUCTION IN LEO
Rockwell International

Figure 11-1. 500 KW Geosynchronous Platform

ORIGINAL PAGE IS
OF POOR QUALITY

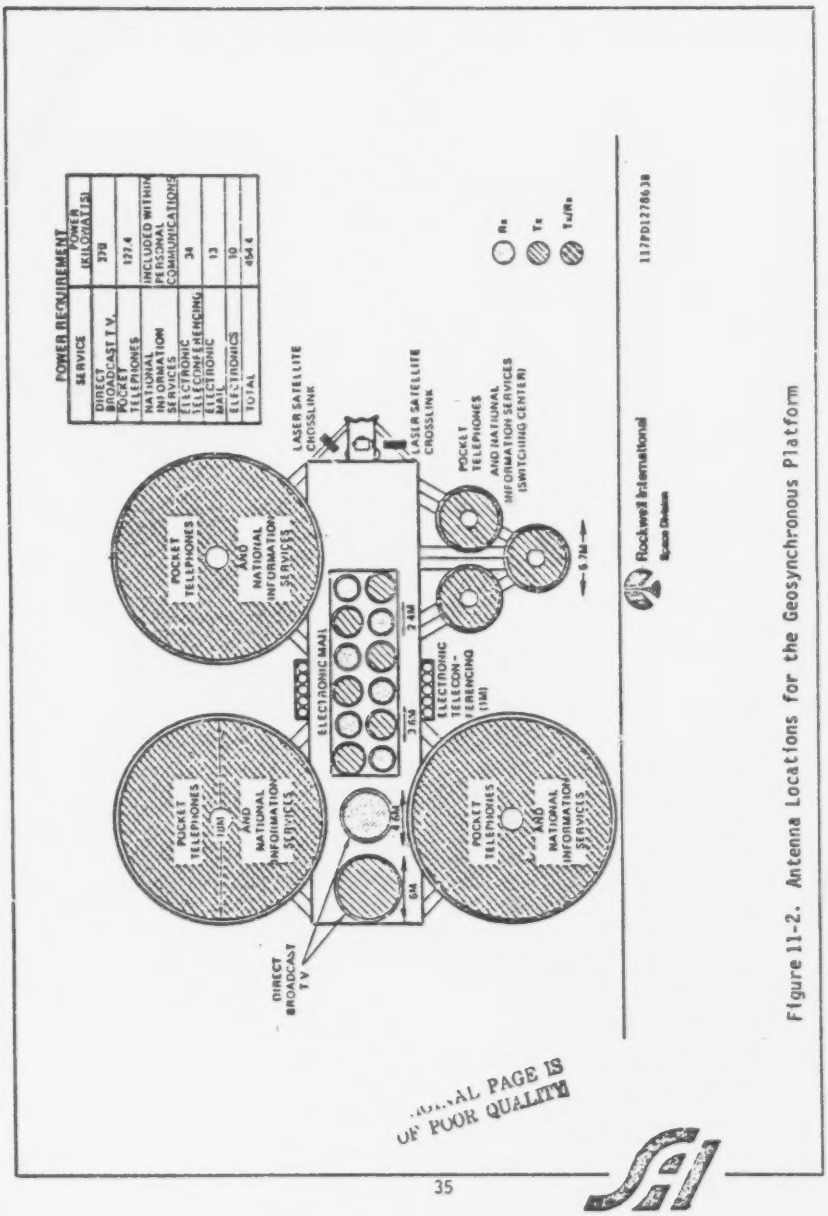

Figure 11-2. Antenna Locations for the Geosynchronous Platform

ORIGINAL PAGE IS
OF POOR QUALITY

The specific functions provided by this early satellite are as follows:

1. Direct broadcast television - Five simultaneous color video channels 16 hours per day to be received on modified, conventional TV receivers. The entire CONUS area is to be covered (excluding Alaska, Hawaii, and Puerto Rico).

2. Pocket telephones - Multiple voice channels originating from remote, wireless extensions; to be connected to conventional fixed terminals or other remote terminals via satellite. Saturation capacity to be at least 45,000 simultaneous transactions.

3. National information services - Direct access via satellite from home or business *intelligent terminals* to computer-supported data banks, such as the Library of Congress.

4. Teleconferencing - Two-way (or multiple) video links between as many as 300 ground sites simultaneously (150 conferences). User locations would have studio-type facilities, including multiple cameras and monitors, switch gear, and communications.

5. Electronic Mail - Facsimile transmission of personal and business correspondence. Terminals would be located in regional postal centers. The regional centers would be interconnected via satellite. Each regional postal center would contain equipment to convert hard copy to electronic facsimile, and vice versa. The ultimate goal is to deliver 40 million pages (8½ x 11) from source to destination over night.

Comparisons to current communications industries were made to derive average figures for net profit margin and non-hardware operational expenses. Rockwell International, in the companion study to this one, derived hardware costs related to these five initiatives for the first platform. Using market projections from Part 1 of the SAI study we derived a prediction of channels needed and sized the space systems requirements and estimated production and deployment costs as a function of time. With all the required cost data together a string of projected costs and revenues was calculated.

In the table below, the "Initial Capital" requirement reflects that amount of money required to establish the service and initiate revenue income. "Capital Before Breakeven" reflects the maximum debt incurred (cumulative cash flow) prior to the cash flow break even time when outlay and income balance. "Rate of Project Return" is an investment judgment tool which allows comparison of economic benefit gained relative to other potential investments. A return of 10% would mean that the investor is breaking even relative to a 10% discounted investment. All figures quoted are computed against a positive future scenario assuming needed structures, power and transportation technologies will come to pass.

SERVICE	INITIAL CAPITAL	CAPITAL BEFORE BREAKEVEN	RATE OF PROJECT RETURN
PERSONAL COMM	$420M	$420M	14%
ADVANCED TV	$200M	$200M	17%
NATIONAL INFO	$420M	$620 – $640M	17%
TELECONF	$254M	$2126M	11%
ELECTRONIC MAIL	$4,260M*	—*	—

*STRONG FUNCTION OF ASSUMPTIONS. BREAKEVEN NEVER ACHIEVED FOR POST OFFICE TO POST OFFICE SYSTEM ASSUMED HERE.

The string of costs and revenues are presented graphically in Figure 11-3 with the number of years to achieve breakeven specified. It was not possible in this study to optimize the R&D investment, debt, market penetration rates, technical synergy and other factors affecting these curves. Also, a more aggressive market scenario could easily lead to economies of scale not realized here. Thus we feel the time to breakeven is generally conservative although not unattractive considering the tens of billions of dollars potential annual revenue.

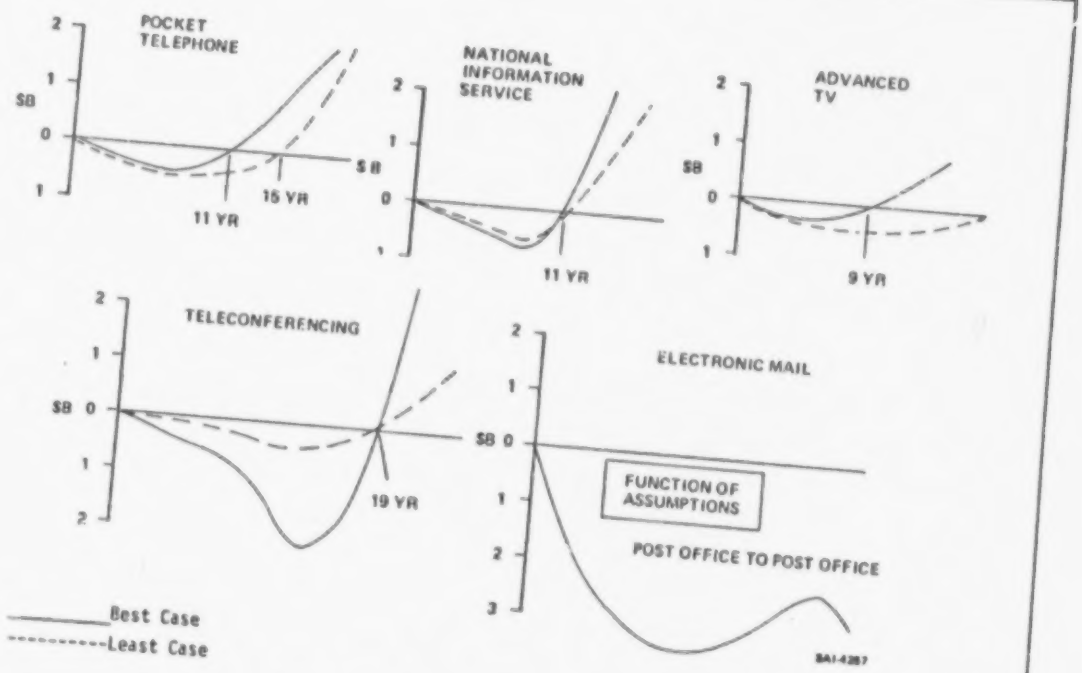

Figure 11-3. Cumulative Cash Flow Requirements

12. OBSERVATIONS AND RECOMMENDATIONS

Many of the results of this study are contained in the various sections of this report as data, observations or conclusions. Recommendations gleaned from outside sources (the industrial contacts) are presented in Volume 3. The purpose here will be to summarize data of particular interest to NASA and the industrial community and present a simple set of recommendations designed to promote the growth of Space Industrialization (SI).

12.1 OBSERVATIONS

Figure 12-1 summarizes the How and Why of Space Industrialization. The roles and related activities of government and industry feed the integrated SI activities that represents the summation of all future private and public SI programs. The motivators for such input and sponsorship are shown as a feedback loop. Three encompassing benefits to the public at large are shown as the integrated "value generation" of space industrialization. Net value generation is possible because a new and virtually inexhaustable resource, loosely called "space", is being utilized.

The corollary consideration of What and When are primarily addressed in Volume 2. At the highest aggregation level (general industrial category) the what and when can be displayed as in Figure 12-2. The rather sterile lines on this figure are wholly inadequate to express the latitude that each has according to the scenario assumed and the realities of capitalization and investment. Also the natural or "organic" growth potential of existing space industry (such as Intelsat and COMSAT) are not reflected on Figure 12-2. Thus the potential exists for the curves of each industry to swing toward greater or lesser revenue or benefit. We can say with some confidence that the direction and magnitude of that swing will depend completely on the investments made in the eighties. The technological, legal, institutional, international and regulatory hurdles must all be overcome in concert. The most important, however, is technological. The incentives are sufficiently strong. That, given technical capability, the other hurdles will be overcome. The future of the United States and our system of free enterprise and democracy demand it. Therein lies the challenge to the NASA, the free worlds technological leader in space.

12.2 KEY TECHNOLOGIES

The most important spur to U.S. industry and U.S. world technical leadership will result from development of the following key technologies.

1. Large information systems
   - Structures - Large antenna of 10M to 200 M diameter.
   - Power - 20 KW to 10,000 KW.
   - Data processing - 100 to 1000 times present rate.
   - Transportation to high orbit - routine for maintenance, repair.
2. Materials space processing
   - Laboratory demonstration - goal oriented spar, spacelab.
   - Prototype production - 10 to 100 pounds per day on some products.
   - Orbital support systems - power, structure, stability
   - Low cost transportation to low orbit -<$100/pound to really open market.
3. Large energy systems (use in space, broadcast to earth)
   - Structures - 0.5 KM to 15 KM
   - Power handling - 25 KW to 10 GW
   - Low cost transportation to high orbit - minimum feasible cost.

The projected benefits depend upon commercial operations that can only begin after the key technologies are available. The potential benefits are significant covering a spectrum of national concerns from jobs and balance of trade through standard of living and national pride.

Analysis of future scenarios, markets and resultant programs show that the result will be:

- Millions of jobs created
- Significant national economic growth
- Assurance of a long term favorable balance of trade
- Increased national and world-wide standard of living
- An enrichment of national pride and aspirations
- An invaluable option bank for responding to unforeseen future events

- Increases in knowledge probably unparalleled in the history of civilization

With the shuttle, we have the basis for space industrialization. We can utilize our lead by proper planning and timely implementation. The alternatives are clear---expanding the U.S. economy or face growing international competition.

In summary, the following points support an aggressive coordinated set of space industrialization initiatives in the public and private sectors.

- The revenue potentials exist today--we only lack the systems.
- All industries examined are exportable--the sooner they are available, the sooner we reap the benefits.
- Near term expenditures will create jobs, spur the economy, and be non-inflationary while creating the future.
- The times are right--if we wait they may not be.
- We can not exploit the shuttle if we don't know where we are going.
- Serious international competition is rapidly building.

The U.S. should begin actively supporting space industrialization by producing a major space power system, initiating the development of systems to support orbital manufacturing and developing large information systems. Substantial space power is needed for almost any industrialization. Materials manufacturing in orbit will require considerable demonstration and supporting systems. Large space information systems look the most commercially viable but the orders of magnitude scale-up needed will require demonstration, and legal constraints (e.g., frequency allocations) may prove very troublesome.

This study has shown that commercially viable industries in Information Services, Energy and Products can be realized given the tools illustrated in Figure 12-3 for private enterprise to work with. Our analysis has also shown that public investment in these capabilities in the eighties will be paid back manyfold in the nineties and beyond. All indications are that Space Industrialization is the stimulus required to swing the United States and the world upward toward the next plateau of human

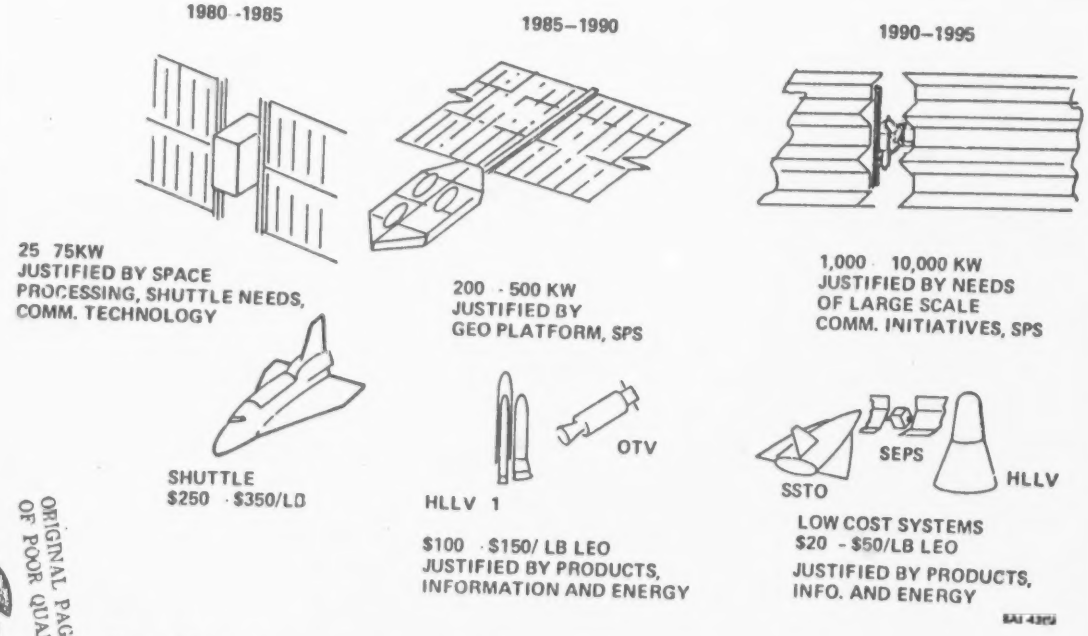

Figure 12-3. SI Structures, Power and Transport Requirements

ORIGINAL PAGE IS
OF POOR QUALITY

achievement. This will be achievement in toto, not just in space or on the Earth but throughout the sphere of human endeavor. We believe that implementation of our recommendations and aggressive pursuit of the overarching concept of Space Industrialization will be concrete steps toward realization of these achievements.

12.3 RECOMMENDATIONS

The following paragraphs contain a series of "key recommendations" that are central to the issue of enhanced SI growth. A broad spectrum of recommendations were formulated, most of them very obvious in derivation. An example might be: "Develop close working relationships with other government agencies and apply SI to their problems and needs." Such recommendations, although central to some aspects of SI growth, are so obviously important that they are already being pursued.

The recommendations presented here, both general and specific, were selected based on their implementation implications. An inherent assumption is that a desire exists to take some predetermined actions to promote the growth of Space Industrialization. Given that assumption, a framework was formulated to provide overall planning guidance and more specific near term steps.

12.3.1 General Recommendations

In the simplest statement, these recommendations are as follows:

- Establish goals for SI in concert with various government agencies and private industry. Most will be in the eighties but some must be identified for the nineties and beyond to obtain overall guidance.
- Plan for the involvement of, and transition to, private industry at the earliest opportunity of all SI initiatives with public services becoming a customer. Consensus opinion is that this will maximize public benefit.

Space Industrialization is, as Ehricke termed it, the overarching concept capable of encompassing and coordinating future applications of space in the most beneficial manner. The individual initiatives in the industrial activities identified in this study should not be pursued as autonomous projects unto themselves. This study has shown that the concepts

of Space Industrialization are viable; that synergistic relationships are possible and desirable; and that industry/government cooperative planning and implementation are desirable and feasible. For various reasons industry will be loath to establish long term goals that carry near term investment commitments, thus government must lead in planning. The assumption of authority and responsibility by industry at an appropriate point in the life cycle of an initiative will require operating characteristics that should be established as part of the design and development process. In this area, industry must lead.

12.3.2 Specific Recommendations

- Incorporate in planning and act on all private industry recommendations discussed in Volume 3.
- Establish an office for SI planning, integration and implementation reporting to the NASA Administrator.
- Conduct the series of studies and formulate/implement the plans shown on Figure 12-4. The subjects and sequences are designed to converge on answers to questions delineated here.

The recommendations most strongly expressed by our industry contacts are presented in Volume 3. Although the level of specificity varies, they are all expressions of a positive nature intended to enhance the near and long term growth of space industrialization.

One recurring message has appeared throughout this study when the origins and reasons for success of various projects was examined. It is that three elements were recurrent. They were:

1. The concept was technically sound.
2. Its evolution was well coordinated and the concepts and developments involved widely displayed.
3. Strong advocacy was provided by a small group of well informed, hard working people.

In recent years a fourth element has often been required: application to an immediate need, although there are notable exceptions in recent years in the scientific community. It is these general observations that prompt our recommendation that a special Office for Space Industrialization Planning, Integration and Implementation be established to focus SI efforts.

Figure 12-4. Recommendations for Study and Planning Activities Leading to Implementation of SI Programs

Figure 12-4 provides a coordinated view of the individual assessments and planning actions which must come together to promote aggressive SI developments in the eighties. A number in parenthesis with each block keys that activity to the detailed description provided in Volume 3. In column one, certain activities have been marked with an asterisk. This denotes studies and assessments of particular importance which should be initiated first if funding or other constraints preclude addressing all of the FY79 list.

The elaborations in Volume 3 provide not only purpose and description but also duration and level of effort which appear appropriate for each activity. These figures are based on experience and judgment developed during this study relative to the difficulty of addressing a particular subject. Hard charging, positive, aggressive program management is assumed in each case.

The overall implementation concept of Figure 12-4 is sound and proceeds as follows:

First, expend sufficient effort to delineate in detail the requirements and problems.

Second, integrate the requirements and find solutions to the problems.

Third, obtain agreements, funding and policy support.

Fourth, implement the plans and programs.

Fifth, continue planning but maintain long term goals.

The details of Figure 12-4 will undoubtedly change as new knowledge is gained. Without such an overall plan and an orchestration of government involvement in SI the sum of benefits that can accrue to the United States probably will not. It appears that private industry can not step up to the total challenge. If the public sector does not, then we are probably witnessing one of the key non-actions leading to the general demise of the United States as a future technological leader. Unless space begins in less than ten years to generate a highly visible return on investment, we can expect an even greater public disinterest than we have previously experienced. At that point the shuttle will be considered a fraud and the whole concept of Space

Industrialization just another way to flim-flam the politicians into wasting money to keep overpaid bureaucrats on the payroll.

Our perceptions from talks, meetings, newspaper articles, etc. from all over the country is that we are being given the "benefit of the doubt". That will not last forever, probably only three or four years into the shuttle era. It will be necessary to extend that horizon to allow the key technologies to mature and really penetrate the commercial applications arena. That time can be gained through two approaches: (1) Implement experimental programs for the early-to-mid-eighties with strong public appeal and visible results. (2) Promote extensive industry/government involvement in every possible area. This will provide evidence that Space Industrialization is real and a genuine goal of the government agencies involved.

Space Industrialization exists and will grow. How rapidly and to what saturation level are the key questions. Acting on our recommendations will assure near optimum growth patterns, benefiting the United States and humankind in general.

Goddard Space Flight Center

Remarks to National Aeronautics and Space Administration Employees at the Facility in Greenbelt, MD. August 30, 1984

The President. Thank you, Jim Beggs. I'm a little self-conscious right now about arriving in kind of an old-fashioned way—in a helicopter. And after what I've seen here, I'm even more self-conscious about the fact that I'm a captain of the horse cavalry. [*Laughter*]

But I'm delighted to be with you today and to have this chance to say congratulations on this morning's lift-off of the *Discovery* mission. I'm honored to meet all of you who are making this great adventure happen. You've sparked the dreams and imagination of the Nation—from the youngest boys and girls in classrooms across our country to individuals like myself who are approaching the outer limits of their middle-age years. [*Laughter*]

You go quietly about your work, far removed from the glare and the gloss and the glitter of public spotlights. But what you do is important. You're expanding our wealth of knowledge, and with that knowledge, you're fueling a mighty tide of progress, carrying the hope of an optimistic future for people here and everywhere.

Yours is the work of a true revolution; not a revolution poisoned by hatred and violence and the will to conquer, but one that's rising from the deepest yearnings of the human spirit that challenge the limits of knowledge and to put the power of discovery at the service of our most noble and generous impulses for decency, progress, and, yes, for peace.

Today, on behalf of a grateful nation, I salute you and your colleagues in private enterprise and the academic world. You're the heroes of high-tech; the pulse of Ameri-

Reproduced from Reagan, Ronald. Goddard Space Flight Center; remarks to National Aeronautics and Space Administration employees at the facility at Greenbelt, Md., Aug. 30, 1984. Weekly Compilation of Presidential Documents, v. 20, Sept. 3, 1984: 1197-1200.

ca's technological power; the champions of a confident people whose faith and courage are pushing America up and out to a world of wonders for us, our children, and our children's children.

The space age is barely a quarter of a century old, but already we have taken giant steps for all mankind. And our progress is a tribute to American teamwork and excellence. We can be proud that we're first, we're the best; and we are so because we're free.

There's nothing that the United States of America cannot accomplish, if the doubting Thomases would just stand aside and get out of our way. In a single generation, we've freed ourselves from the bounds of Earth; we've set our footprints on the surface of the Moon; we've used our instruments to explore space, the Sun, and our sister planets; and our space shuttle provides the first reusable space transportation system for research, commercialization of space, and scientific exploration.

Meeting these great challenges has given us benefits far more valuable than our original investments. It has proven wrong those dreary souls who lacked the vision to support your efforts. With their pessimism, America could never have gotten off the ground. And with your space shuttle, we have again and again. And I'm convinced your success confirms a vision that we share: an America unafraid, reaching into space with courage and leadership, will be an America unsurpassed. We have it within our power to create a bounty of new jobs, technologies, and medical breakthroughs surpassing anything we've ever dreamed before or imagined.

We already benefit daily from a modern revolution in worldwide communications. We can communicate with each other at a moment's notice, virtually anywhere on the globe. We can anticipate tomorrow's weather and prepare for it. Our space shuttle system provides access to space for science, technology, communications, and national security.

Only a few weeks ago, we watched the Olympics on television, sharing excitement with people all over the world. I can remember—and believe me it doesn't seem long ago—when we lived in the horse-and-buggy days of television. We couldn't see a breaking event on the other side of the world until the film was shipped here. But, today, thanks to your research and development work, we have modern communications satellites beaming crystal-clear telecasts worldwide.

Another quiet revolution in technology has also been driven, in part, by the rigors of our space program. New materials from plentiful natural resources like carbon and silicon are taking the place of expensive metals in virtually all manufactured products. Our automobile engineers in Detroit are using lightweight, super-strong, plastic-like materials to reduce the weight of modern cars—and consumers are getting the benefits in the form of more miles to the gallon.

Computers using microchips are constantly redefining our world as they become smaller, more powerful, and less expensive. Those chips are the heart of inexpensive electronic calculators now commonplace in the workplace, community, and classroom.

Sometimes these technological changes take place so gracefully over time that we hardly notice them. Today our children have access to more computer power than most professional scientists and engineers had in their laboratories at the beginning of the space age.

Dr. Robert Jastrow, Chairman of the First NASA Lunar Exploration Committee, predicted nearly 2 years ago that the computer industry would double in size by 1986, becoming America's biggest business. Already, tens of thousands of practical applications of space and aeronautical technology are touching our lives. I've just seen an exhibit here with a vast array of new products from lifesaving vests for firemen to sophisticated aerial-scanning techniques to locate and identify everything from schools of fish to mineral deposits to healthy timberland.

In medicine we're seeing the vision of technology with a human face with one miraculous breakthrough after another. The procedure called CAT scanning uses a computer to compile a clear picture from x rays taken at different angles, often permitting patients to avoid the risks and discomforts of surgery. CAT scanning has come a lifesaver in detecting diseases of the brain and other vital organs.

The pioneer field of computer-controlled walking has given hope to thousands of paralyzed Americans that, someday, they may walk again.

The widespread use of sound waves allows doctors to avoid potentially harmful use of x rays. Using sound waves to monitor the progress of babies inside the womb permits earlier diagnosis of problems, a safer pregnancy and delivery for the mother, and better health for the baby.

HTS, for Human Tissue Stimulator, sends electrical impulses through wire leads to targeted nerve centers or particular areas of the brain, providing relief from pain and stopping unwanted involuntary motion. I'm happy to point out that HTS was sponsored by the Goddard Space Center.

I've also been shown a hand-held x ray machine and the Programmable Implantable Medication System, called PIMS, that administers medication automatically within the body.

It would be difficult to put a pricetag on the value of these human benefits. Even more dazzling opportunities lie ahead, if only we have the faith and courage to keep pushing on. Each technological breakthrough enables us to work from a new and higher plateau. It opens the door to great leaps in productivity which would have been considered unthinkable only a few decades ago.

Permit me to suggest that the fraternity of pessimists, who today insist strong growth will ignite high inflation, are looking at abstract statistics, theories, and models, not the reality of a changing world. They do not see that as we acquire more and more knowledge from new technologies, we no longer move forward in inches or feet; we begin to leap forward.

Working the zero-gravity environment of space, we can manufacture in just 1 month's time lifesaving medicines that it would take 30 years to manufacture on Earth. And we can manufacture crystals of exceptional purity that may enable us to produce super-computers and make even greater breakthroughs in productivity.

Our vision is not an impossible dream; it's a waking dream. As Americans, let us cultivate the art of seeing things invisible. Only by challenging the limits of growth will we have the strength and knowledge to make America a rocket of hope shooting to the stars.

High technology is born from capital, and more capital will require continued incentives for risktaking and investment, not tax increases, which would stifle growth. We support high-tech, not high taxes. The Federal Government must constantly endeavor to strengthen the private economy, while supporting research and development, particularly in universities, to train tomorrow's industrial and academic scientists and engineers.

Our agenda for excellence in education at the elementary and secondary school level is also crucial, so students, like those I met at Jefferson Junior High School on Monday, can acquire the knowledge to enter universities and, one day, step into these vital positions of leadership and responsibility.
